

Machine Learning per la fisica applicata e la fisica delle alte energie

Prof. Simon Badger
Quinto piano EN 9
[simondavid.badger at unito.it](mailto:simondavid.badger@unito.it)

Schema del corso

motivazione

Femenologia in collider ad alte energie

Dalle teorie di campi alle esperimenti

Simulazione teorica

l'alto costo della integrazione numerica

Machine Learning per fisica fondamentale

Come puo ML aiutarci a capire le legge di Natura?

Schema del corso

practica

Ottimizzazione di simulazioni

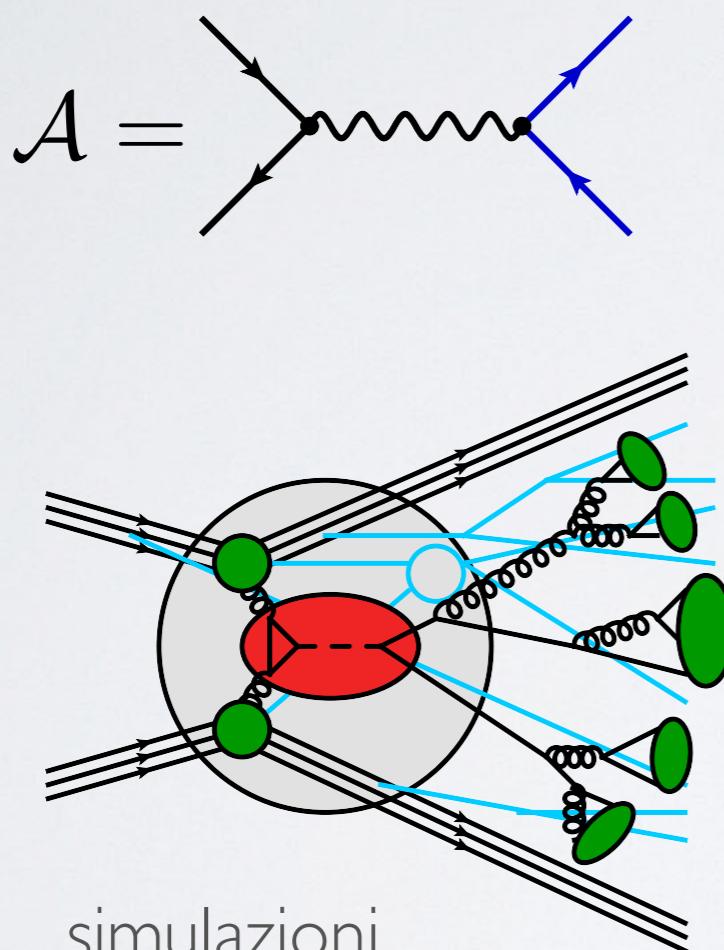

- Problemi di regressione (riepilogo)
- Reti neurali
- Ampiezza di scattering
- Errori?
- Event generation

Scegliere i osservabili migliori

- Classification problems
- Jets and jet substructure

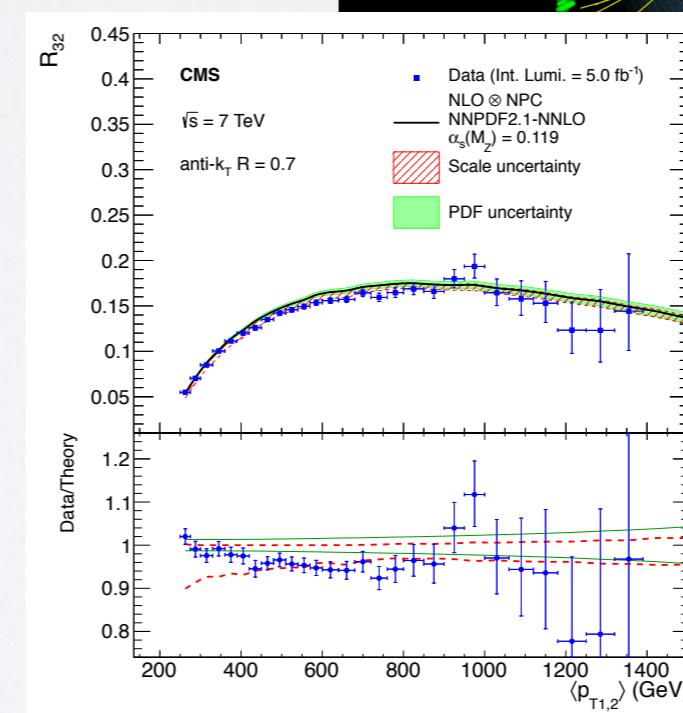

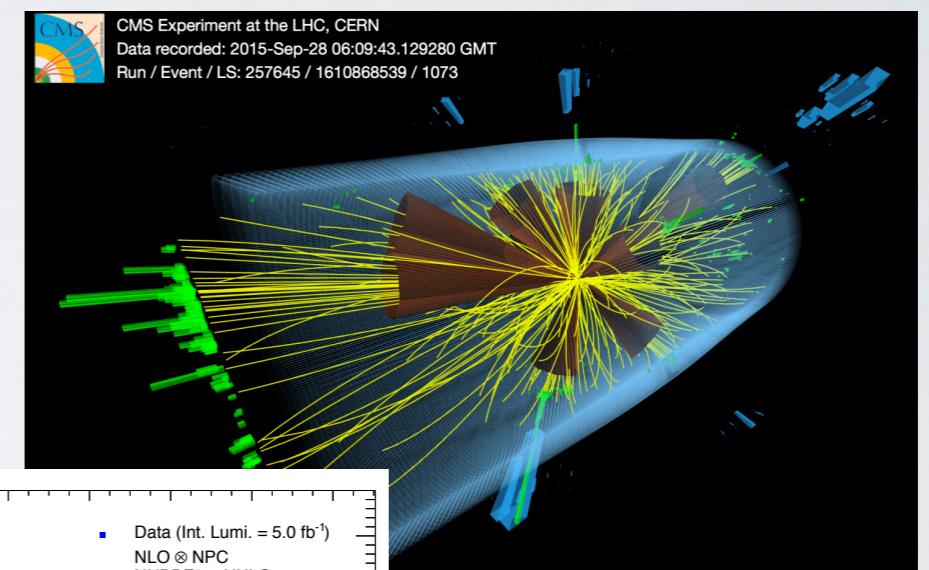

I. Introduzione alla fisica del collisore

ampiezza

simulazioni

rivelatori (detectors)

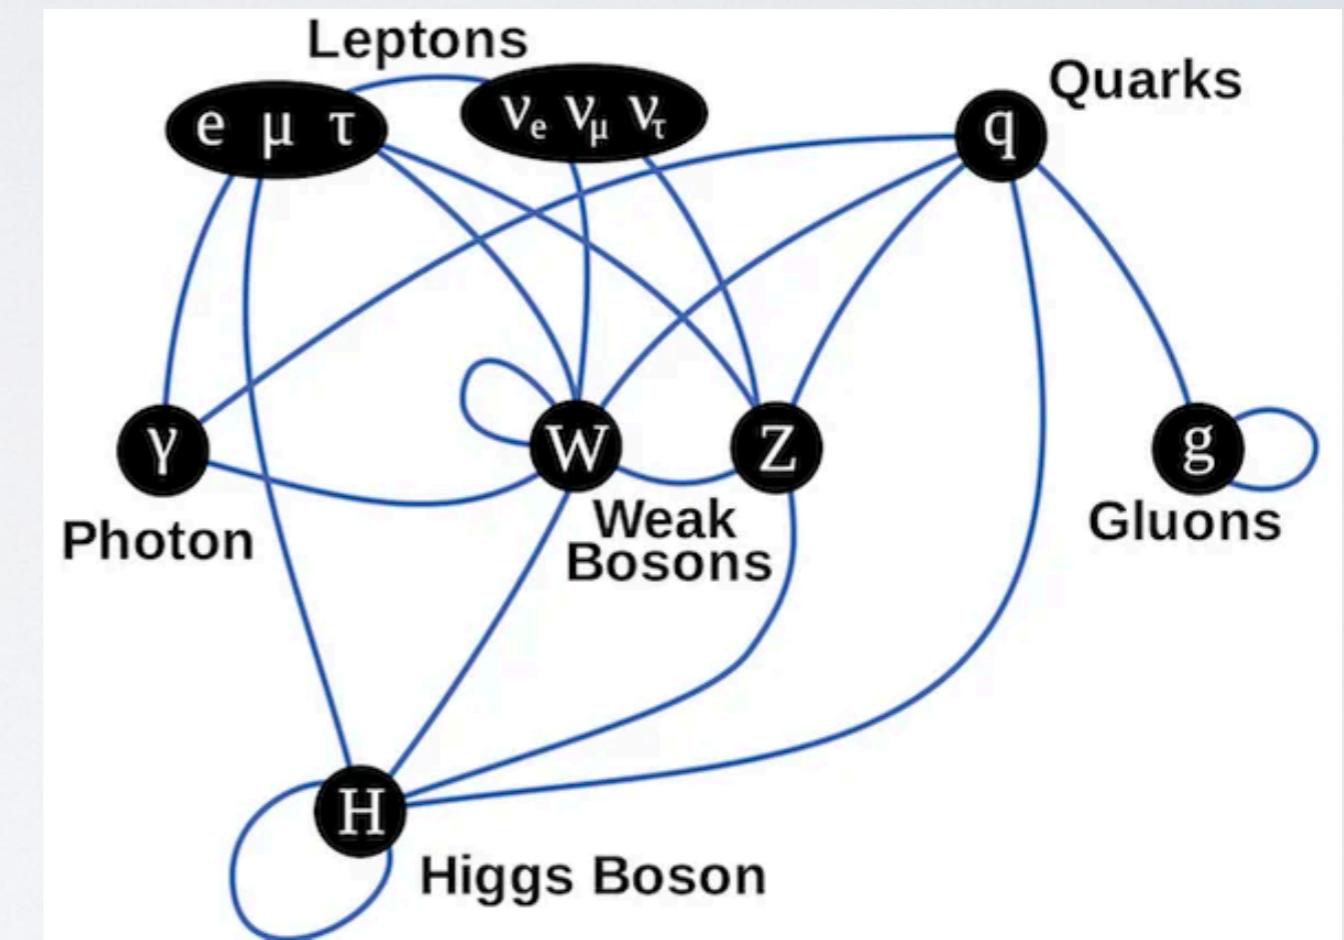

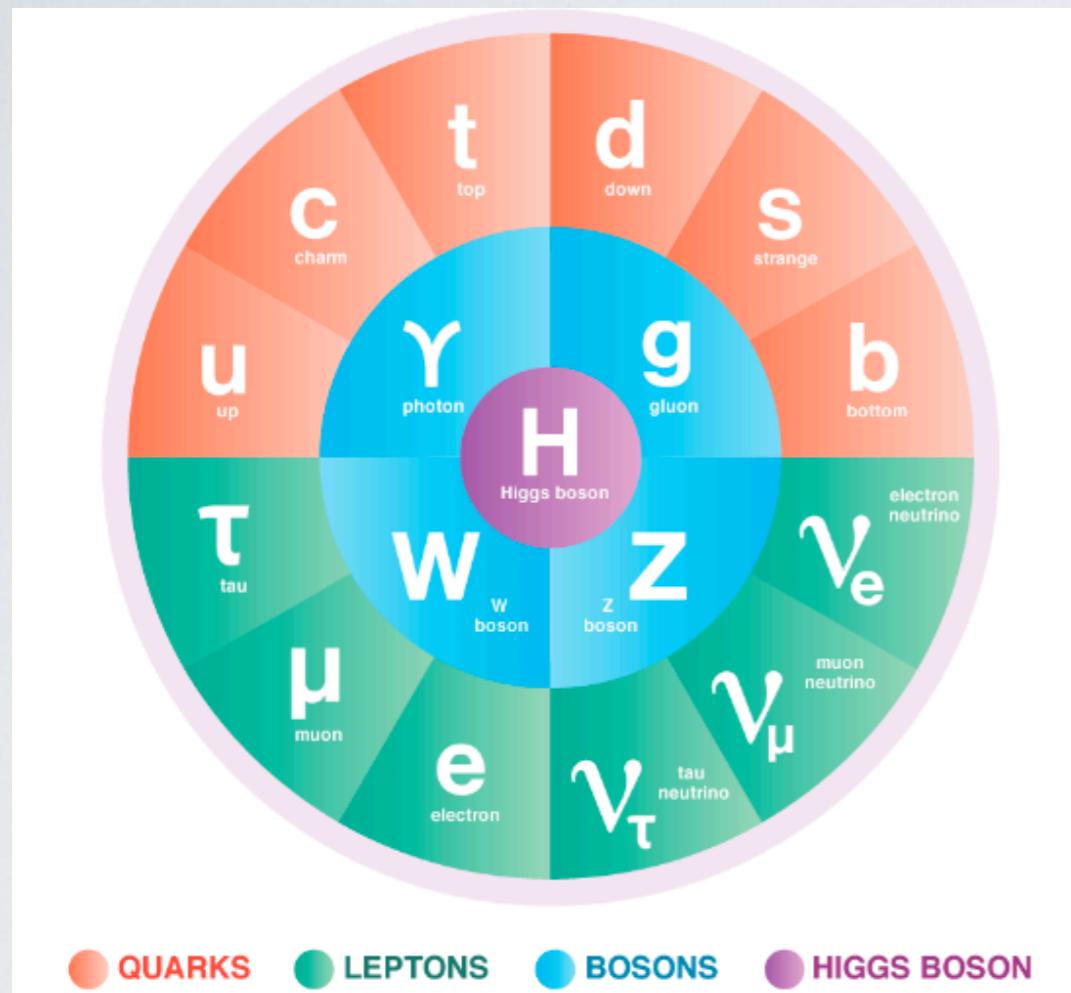

fenomenologia

$$SU(3)_c \times SU(2)_L \times U(1)_Y$$

Standard Model of Elementary Particles

three generations of matter (fermions)			interactions / force carriers (bosons)	
	I	II	III	
QUARKS	mass $\approx 2.2 \text{ MeV}/c^2$ charge $\frac{2}{3}$ spin $\frac{1}{2}$	mass $\approx 1.28 \text{ GeV}/c^2$ charge $\frac{2}{3}$ spin $\frac{1}{2}$	mass $\approx 173.1 \text{ GeV}/c^2$ charge $\frac{2}{3}$ spin $\frac{1}{2}$	mass 0 charge 0 spin 1

$$SU(3)_c \times SU(2)_L \times U(1)_Y$$

Scattering alle alte energie

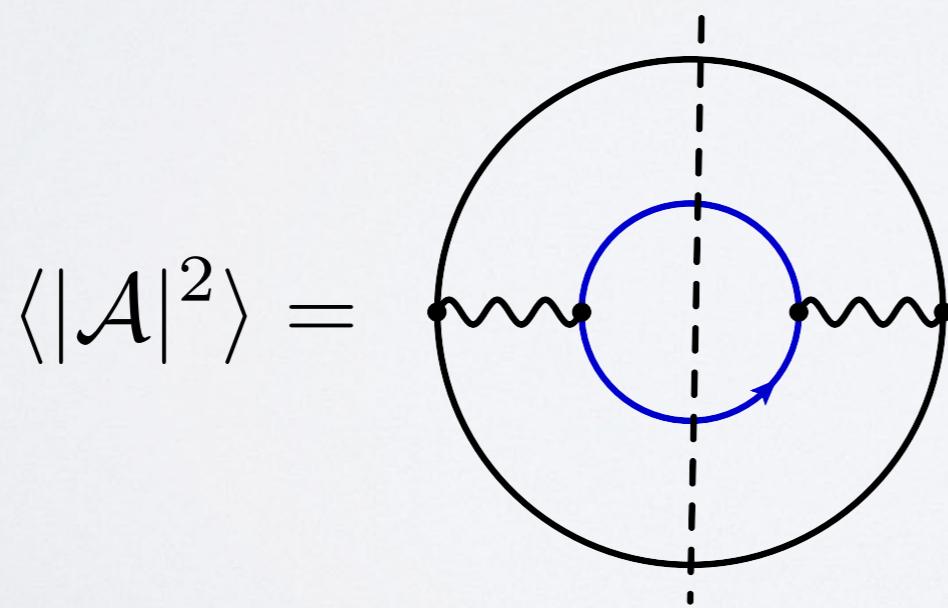

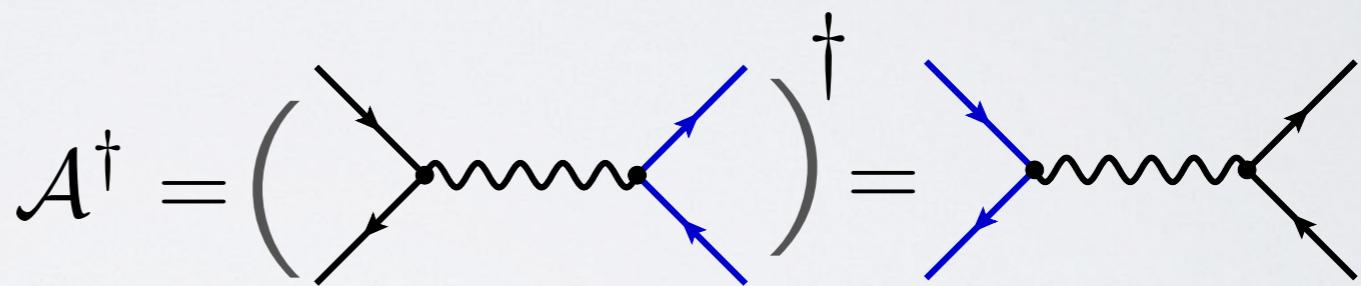

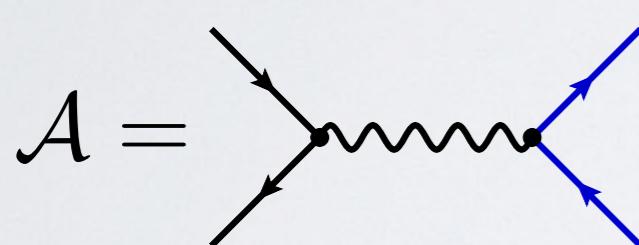

$$\sigma = \frac{1}{\text{flux}} \int \delta^{(4)}(Q - \sum_i p_i) \prod_i d^4 p \delta^{(+)}(p_i^2 - m_i^2) \langle |\mathcal{A}|^2 \rangle$$

e.g.

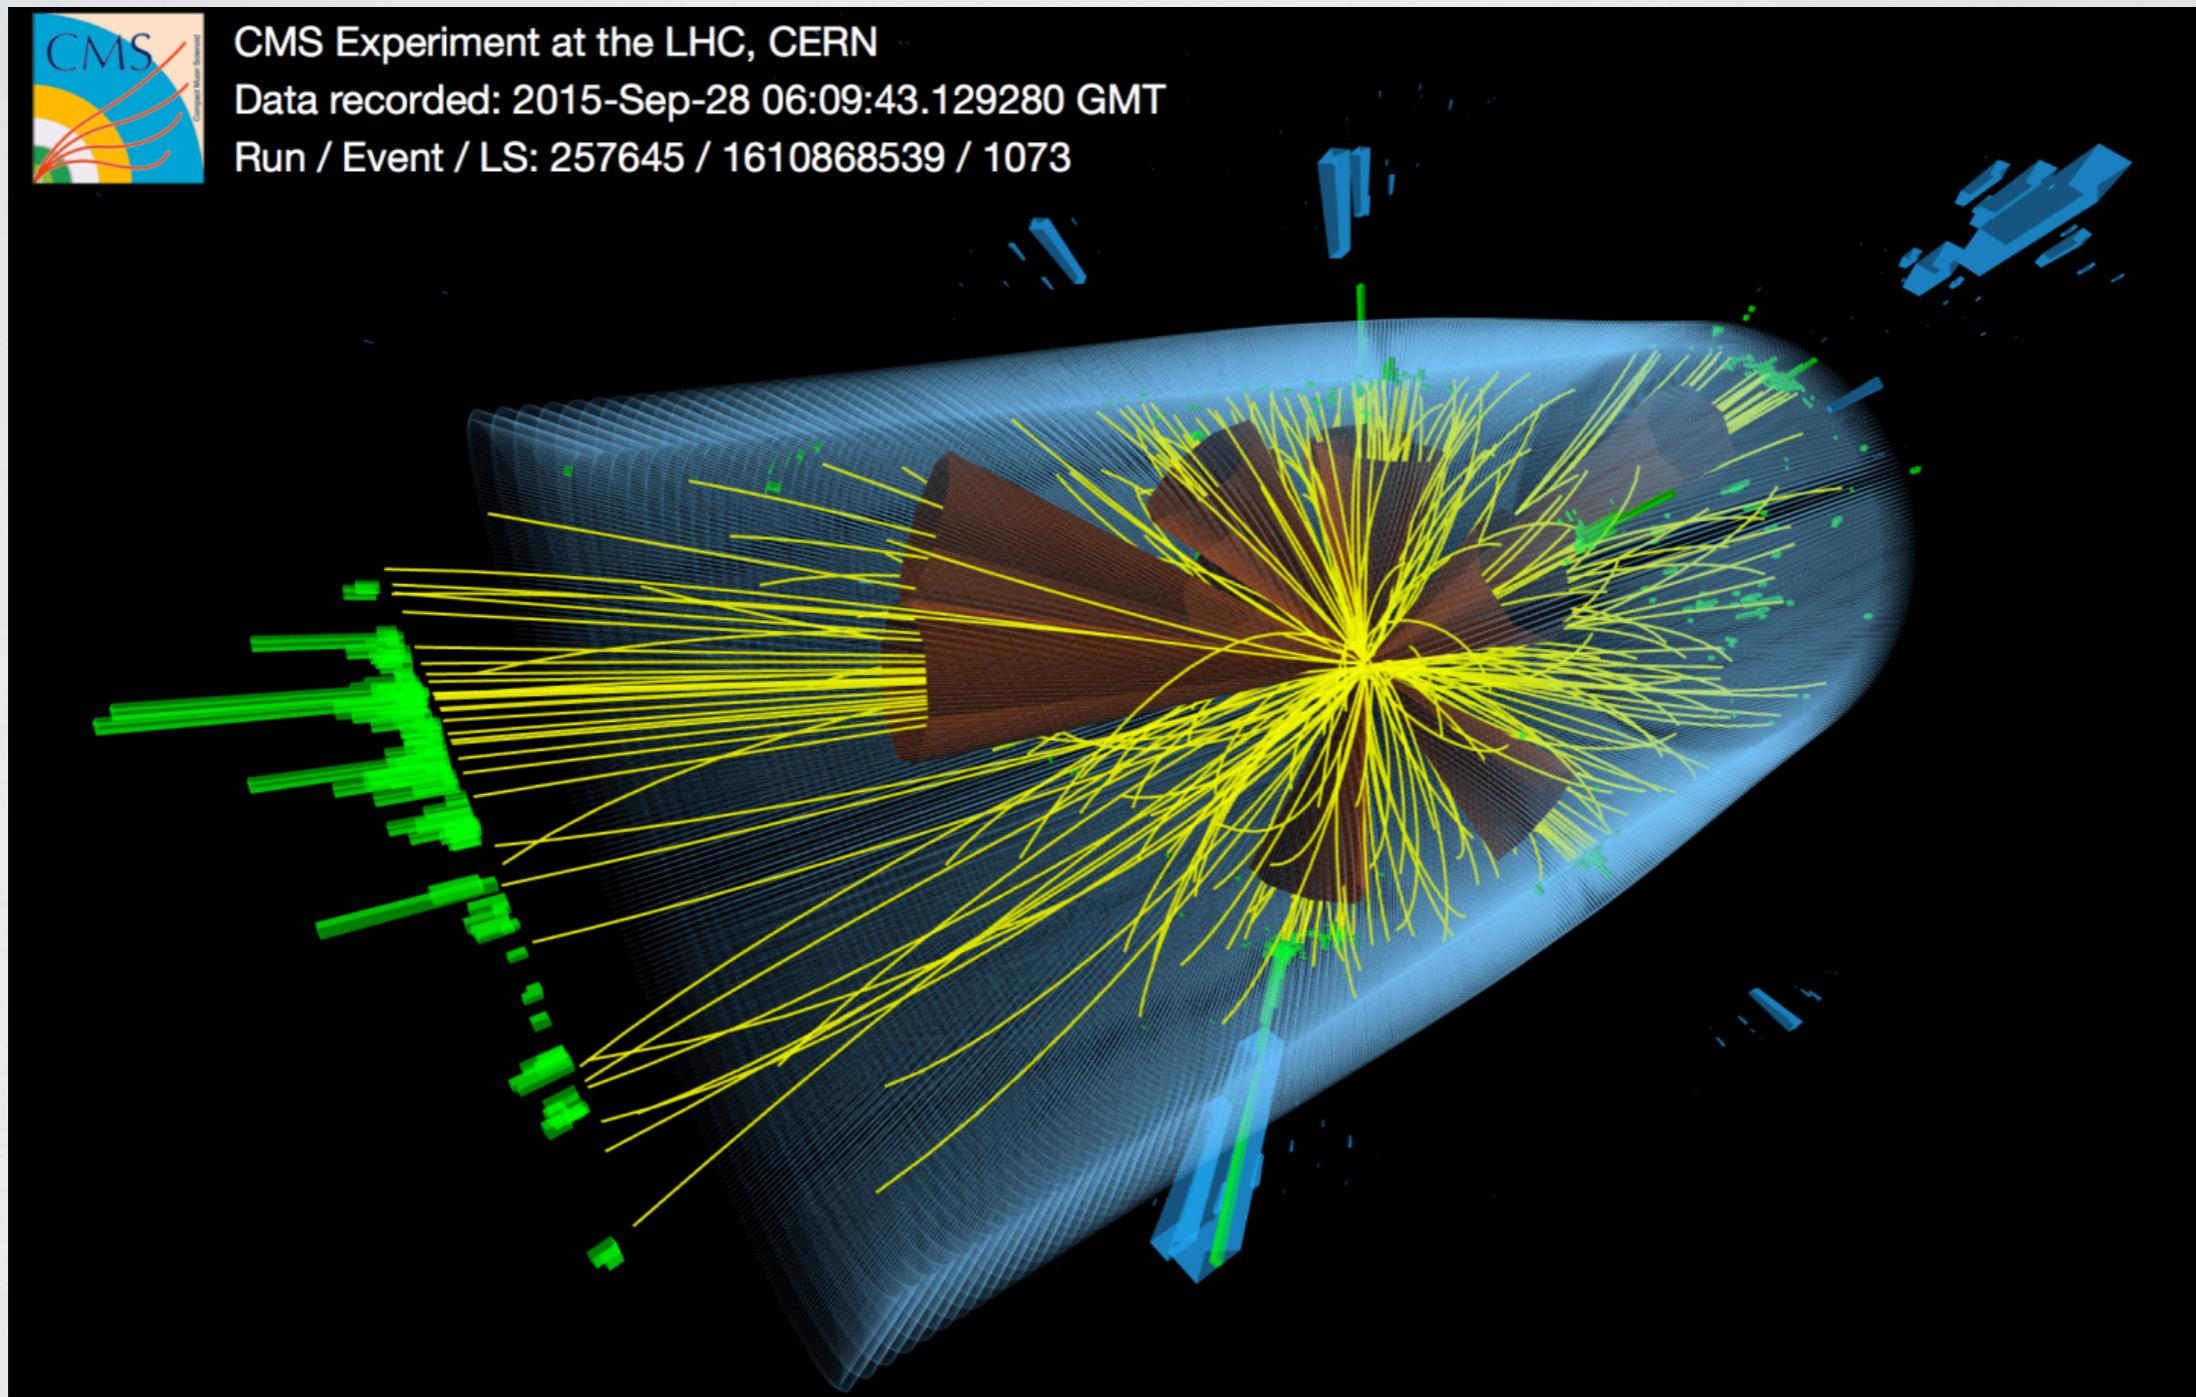

Aampiezza di scattering : probabilità dalla Lagrangiana

$$\langle |\mathcal{A}|^2 \rangle = \sum_{\text{spins}} \mathcal{A}^\dagger \mathcal{A}$$

diagrammatic
representation of the
squared amplitude

Cosa vedono i esperimenti?

Cosa vedono i esperimenti?

tracking detectors

calorimeters

exclusive particle identification

(see π , p , J/ψ NOT u,d,c,g)

unstable particle decay

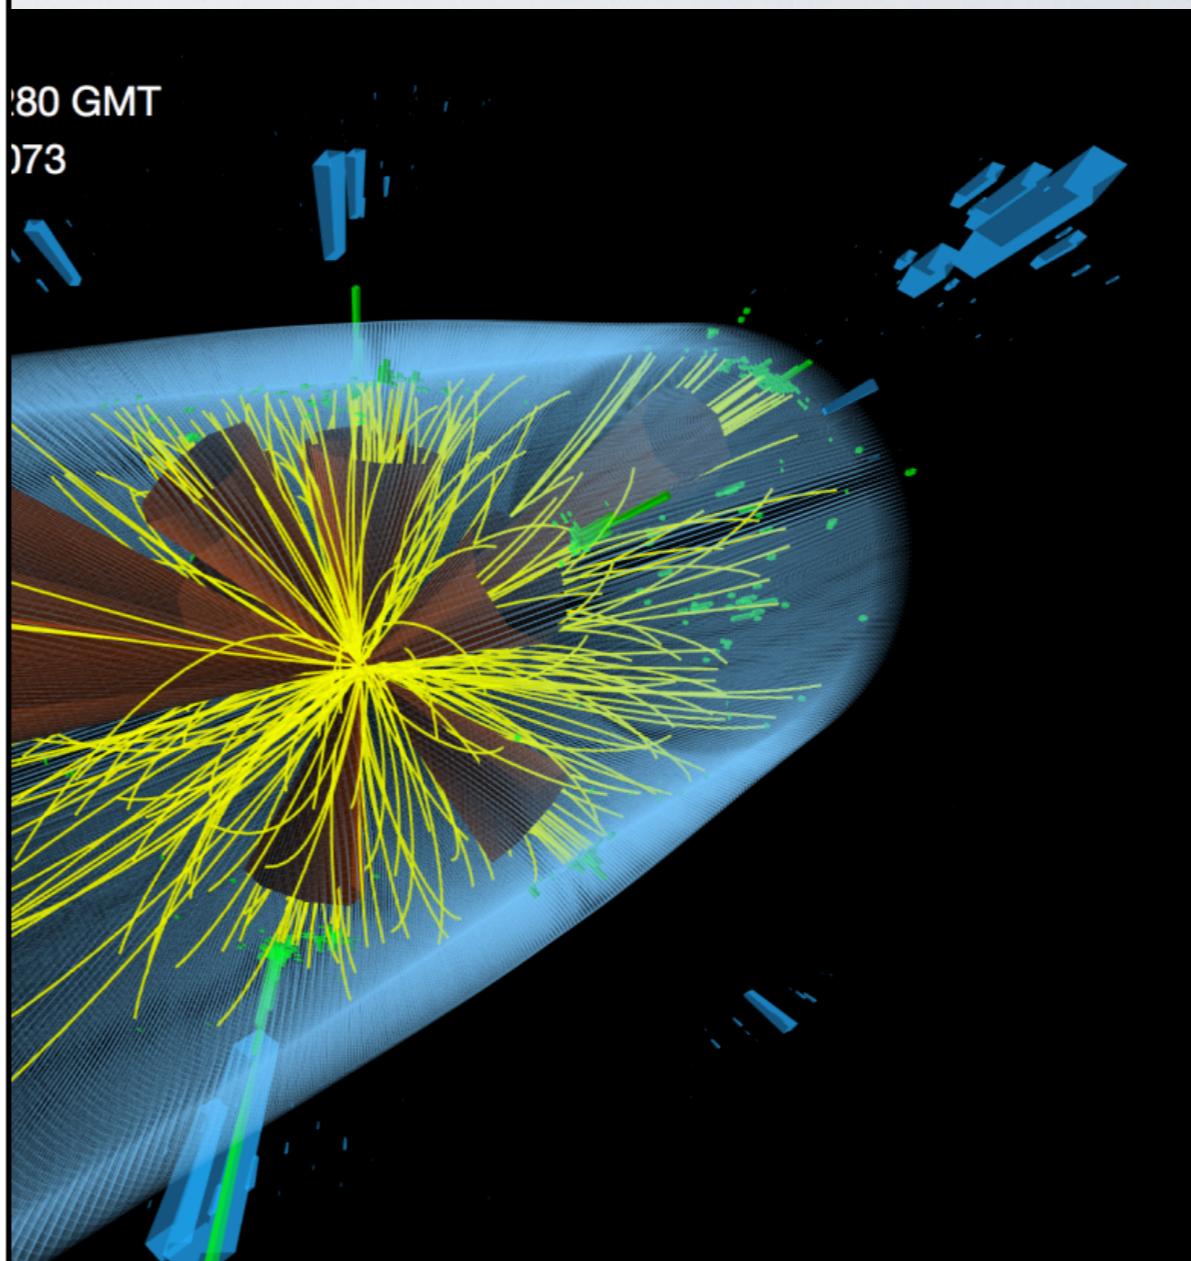

(see e,μ,b NOT W,Z,H,t)

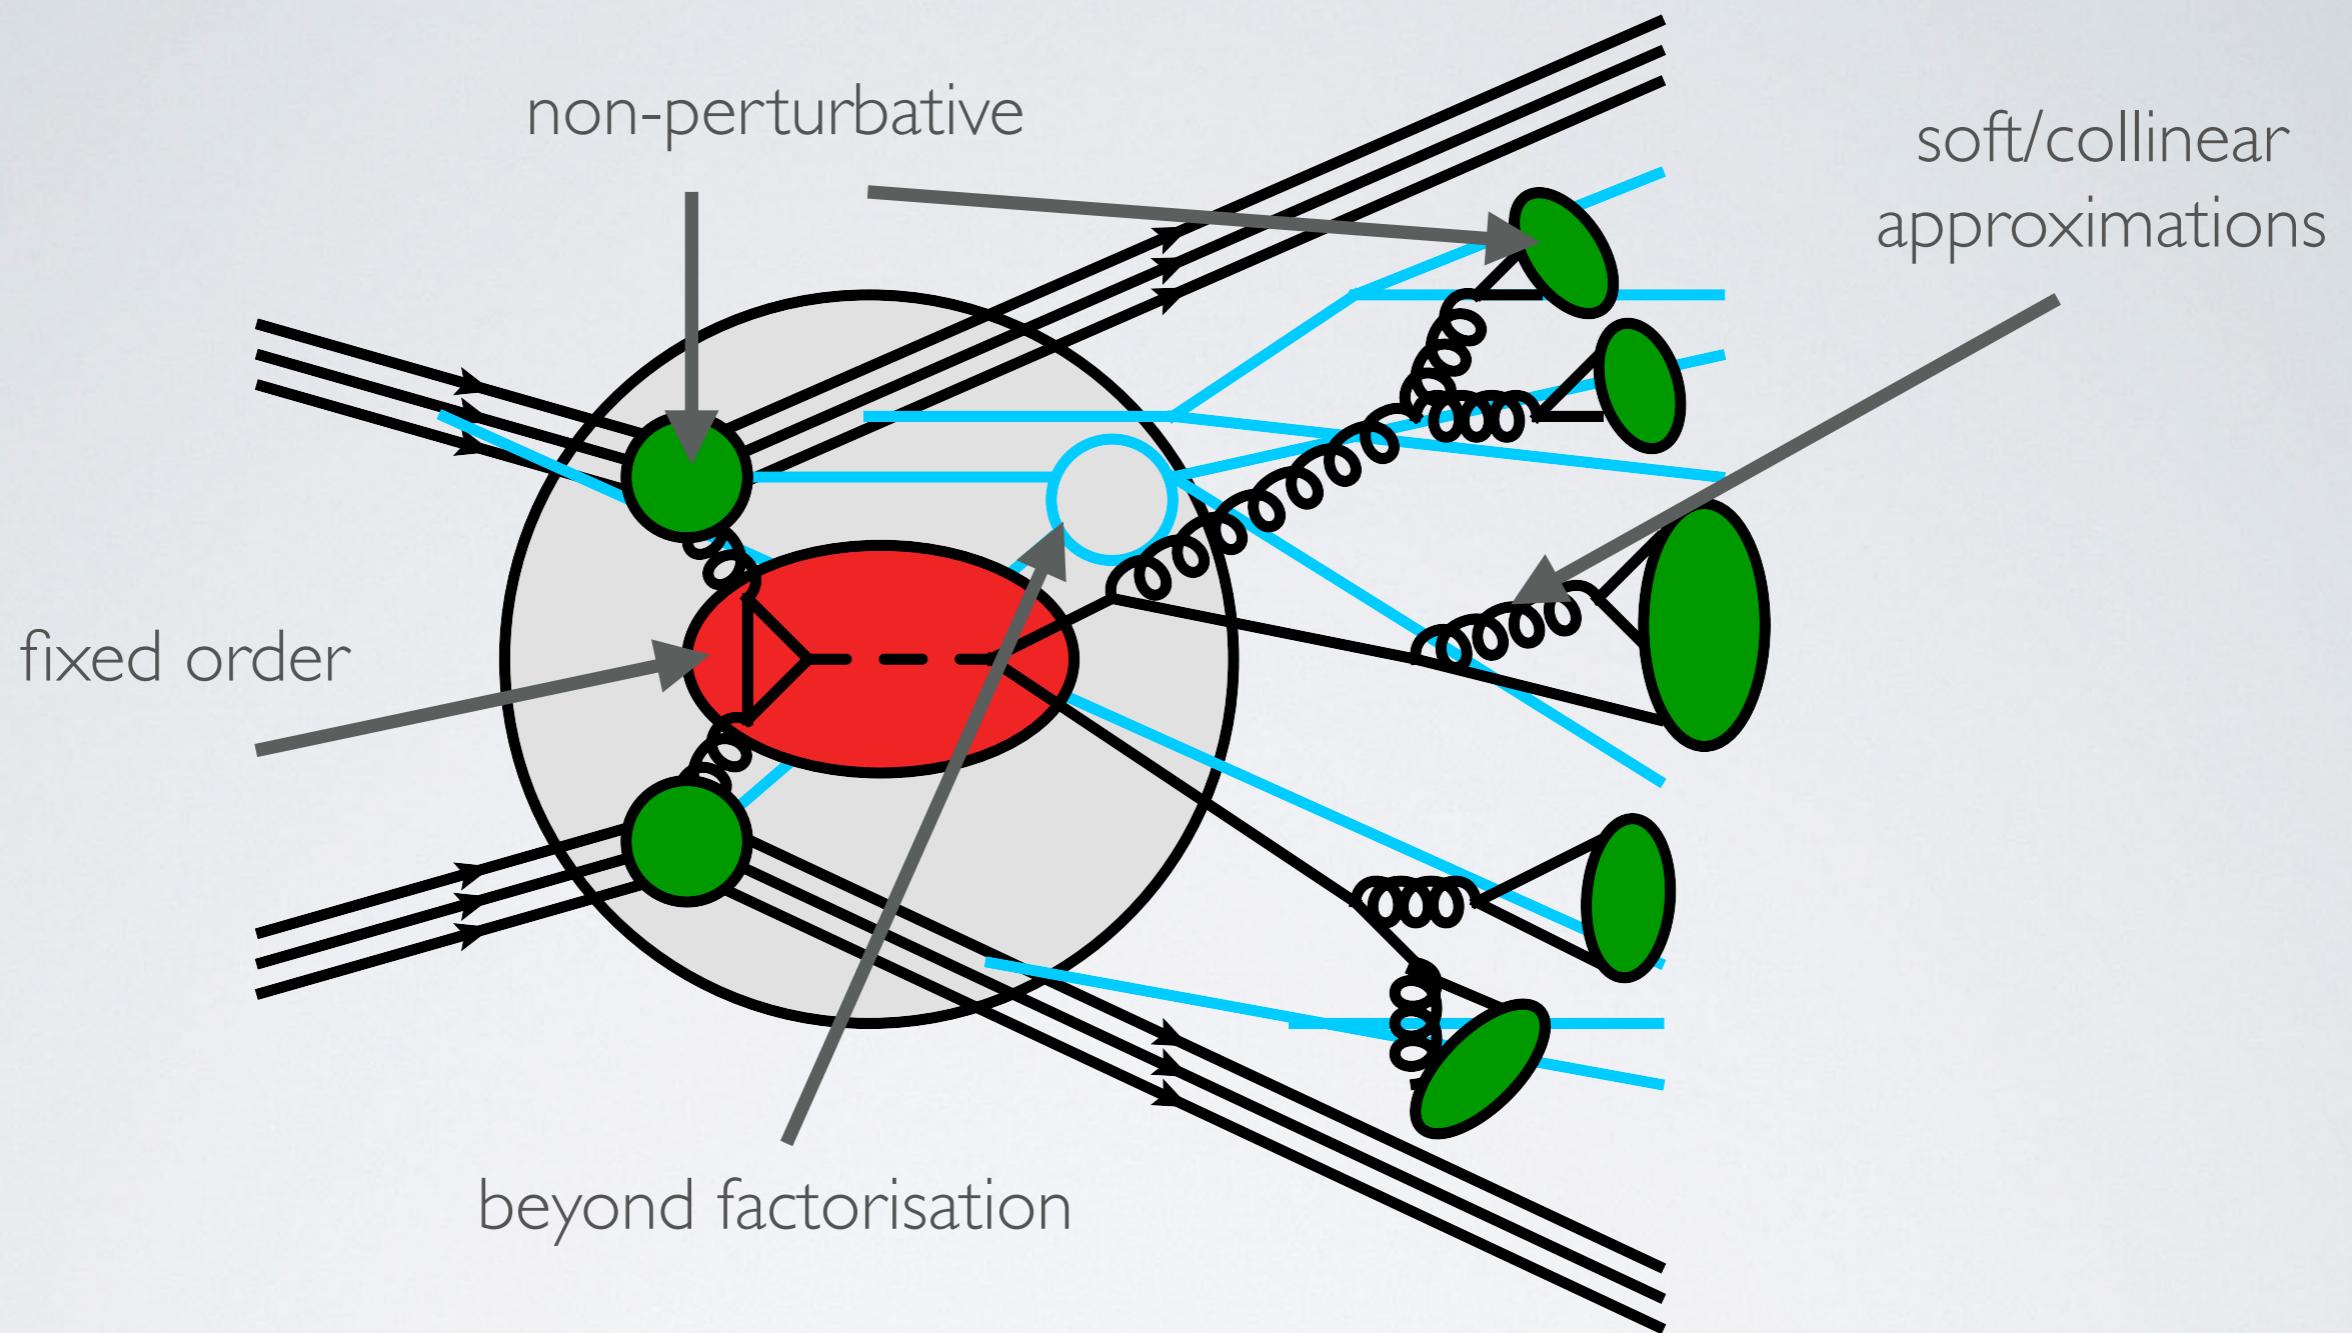

there will be missing energy

(can't see ν)

precise physical dimensions!

(need fully differential theory predictions)

numerical simulations using Monte Carlo integration

'Monte Carlo Event Generators'

Scattering ad alte energie ancora; factorisation per collisore adronico (LHC)

$$\hat{\sigma} = \frac{1}{\text{flux}} \int \delta^{(4)}(Q - \sum_i p_i) \prod_i d^4 p \delta^{(+)}(p_i^2 - m_i^2) \langle |\mathcal{A}|^2 \rangle$$

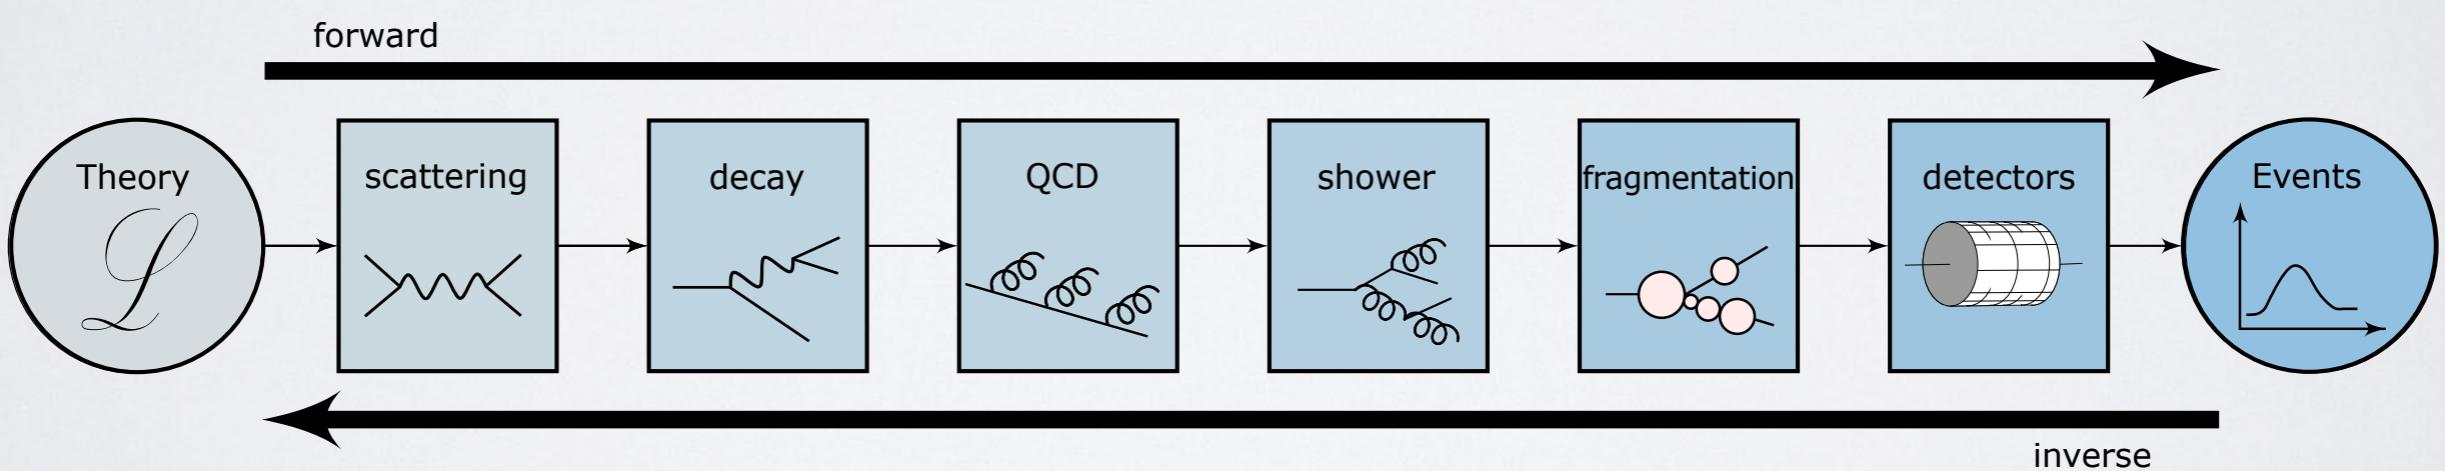

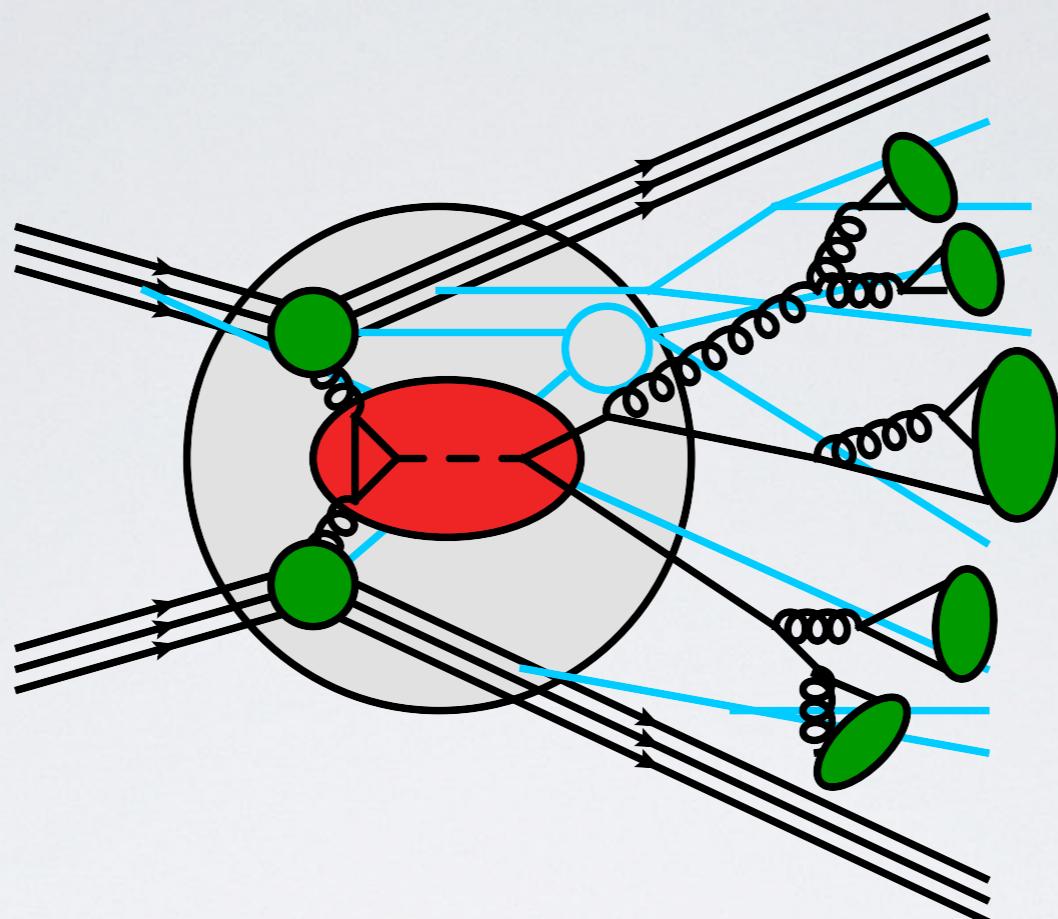

$$\sigma \sim \int dx_1 dx_2 f_i(x_1, Q^2) f_j(x_2, Q^2) \hat{\sigma}(ij \rightarrow \{p\}) \Theta + \mathcal{O}(Q/\Lambda)$$

PDF
parton distribution function

observable
(very broad definition)

beyond leading
order factorisation

The diagram illustrates the decomposition of the cross-section σ into three components. Three arrows point from the text labels below to the corresponding terms in the equation. The first arrow points to $f_i(x_1, Q^2) f_j(x_2, Q^2)$, labeled 'PDF parton distribution function'. The second arrow points to $\hat{\sigma}(ij \rightarrow \{p\})$, labeled 'observable (very broad definition)'. The third arrow points to $\Theta + \mathcal{O}(Q/\Lambda)$, labeled 'beyond leading order factorisation'.

what precision do we need?

determination of
SM parameters

a lot!

general searches for
BSM resonances

less...

Many experimental measurements approach 1% precision

e.g. Drell-Yan with ATLAS (2019)

	Data
$\sigma(W^+ \rightarrow \mu^+\nu)$ [pb]	3110 ± 0.5 (stat.) ± 28 (syst.) ± 59 (lumi.)
$\sigma(W^- \rightarrow \mu^-\bar{\nu})$ [pb]	2137 ± 0.4 (stat.) ± 21 (syst.) ± 41 (lumi.)
Sum [pb]	5247 ± 0.6 (stat.) ± 49 (syst.) ± 100 (lumi.)
Ratio	1.4558 ± 0.0004 (stat.) ± 0.0040 (syst.)

QCD is the largest coupling and so dominates the perturbative expansion

$$\alpha_s(M_z^2) = 0.117 \pm 0.0009$$

PDG world average (2021)

$$\text{c.f. } \alpha^{(-1)}(0) = 137.035999150(33)$$

$$d\sigma = \boxed{d\sigma^{\text{LO}}} + \boxed{\alpha_s d\sigma^{\text{NLO}}} + \boxed{\alpha_s^2 d\sigma^{\text{NNLO}}}$$

~10-30 %

~1-10 %

remember:
RG improved PT
is asymptotic

differentially many effects play a role: EW corrections, mass effects etc.

Making Precision Predictions

As mentioned before QFT contains divergences in both **UV** and **IR**

observables such as (differential) cross sections must be **inclusive** over the phase-space in order to capture the cancellations from **unresolved** radiation configurations

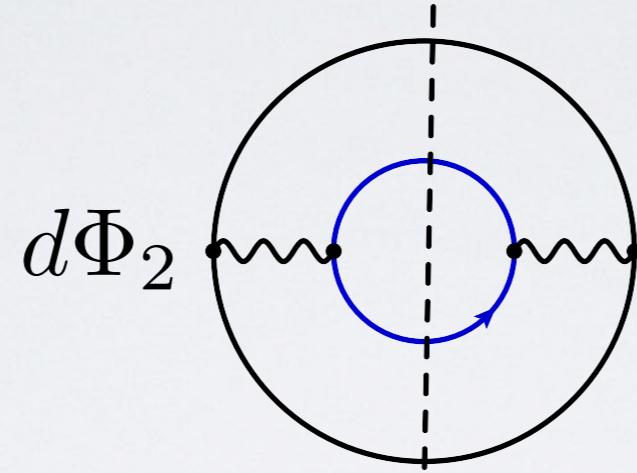

$$\sigma \left(\text{diagram} + X \right) = \int d\Omega_1 \left(\text{diagram} \right)^2 + \int d\Omega_2 \left(\text{diagram} \right)^2 + \int d\Omega_3 \left(\text{diagram} \right)^2 + \dots$$

now consider the perturbative expansion of these amplitudes

Making Precision Predictions

QCD corrections to $e^+e^- \rightarrow q\bar{q}$

LO

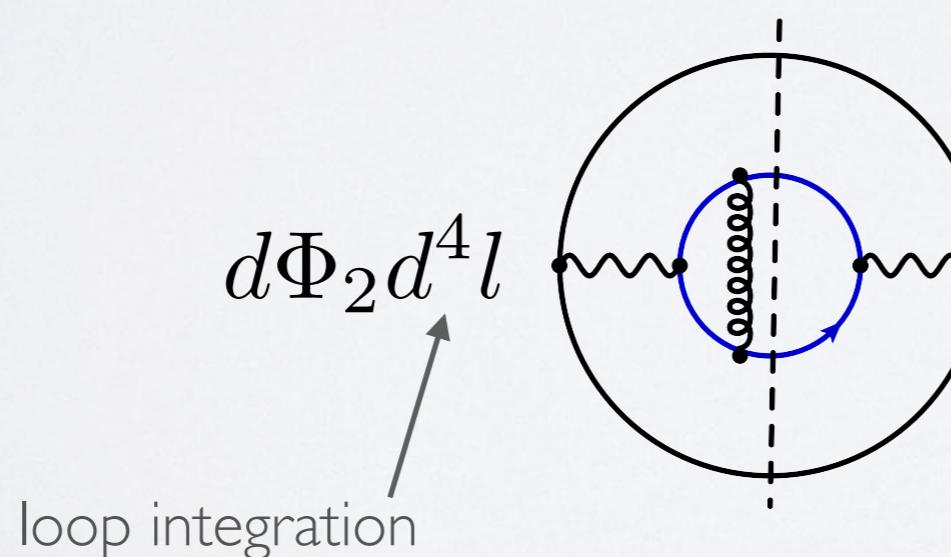

'Born'

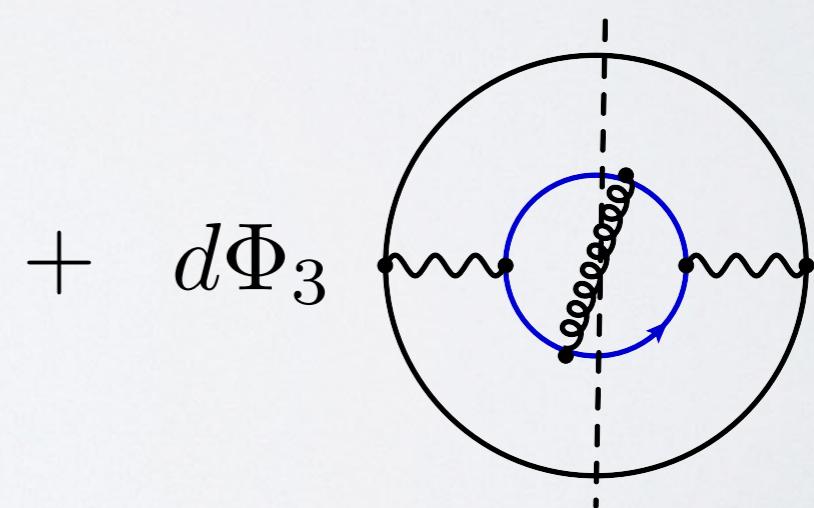

IR divergences cancel between real and virtual corrections to physical observables.

Kinoshita-Lee-Nauenberg (KLN) theorem

NLO

'Virtual'

'Real'

Making Precision Predictions

The full calculation involves many steps and techniques...

$$\sigma^B(e^+e^- \rightarrow q\bar{q}) = \frac{4N_c \alpha^2 q_q^2}{3\pi s}$$

dimensional regularisation

$$d = 4 - 2\epsilon$$

$$\sigma^V(e^+e^- \rightarrow q\bar{q}) = \sigma^B C_F \frac{\alpha_s}{2\pi} \mathcal{H}(\epsilon) \left(-\frac{2}{\epsilon^2} - \frac{3}{\epsilon} - 7 - \delta^{CDR} + \pi^2 \right)$$

scheme dependence

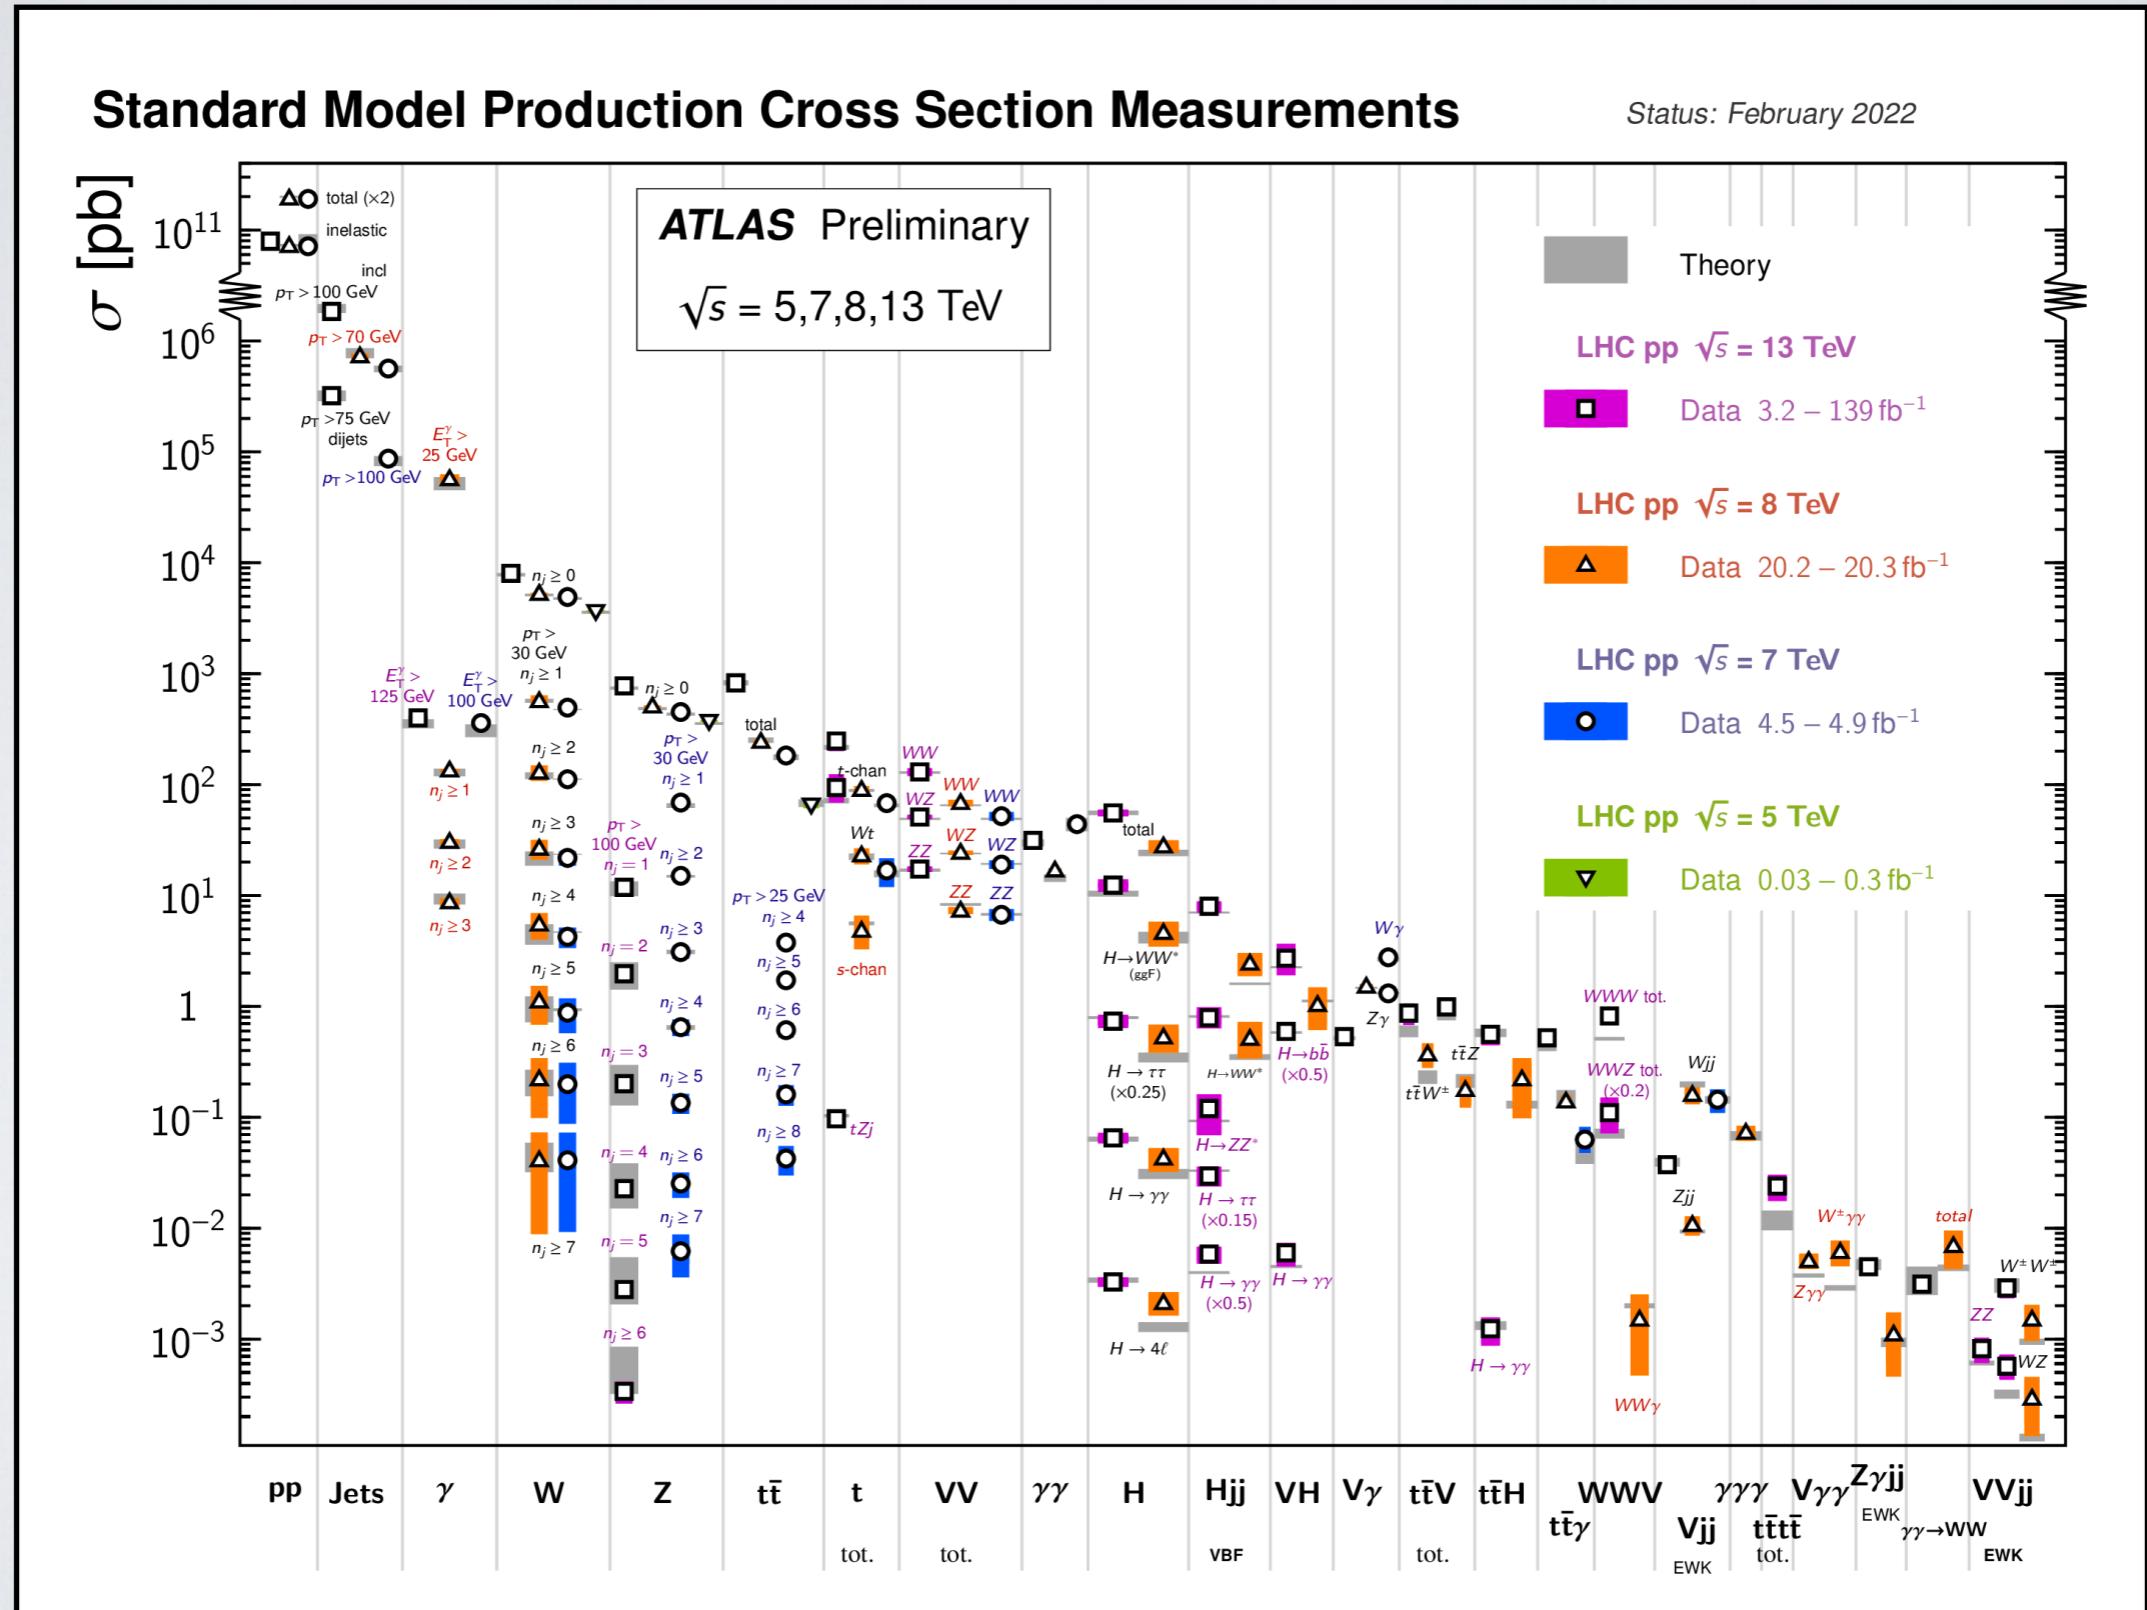

$$\sigma^R(e^+e^- \rightarrow q\bar{q}) = \sigma^B C_F \frac{\alpha_s}{2\pi} \mathcal{H}(\epsilon) \left(\frac{2}{\epsilon^2} + \frac{3}{\epsilon} + 17/2 + \delta^{CDR} - \pi^2 \right)$$

$$R = N_c \sum_{q=\{u,d,s,\dots\}} \Theta(\sqrt{s} - 2m_q) q_q^2 \left(1 + C_F \frac{3\alpha_s}{4\pi} \right)$$

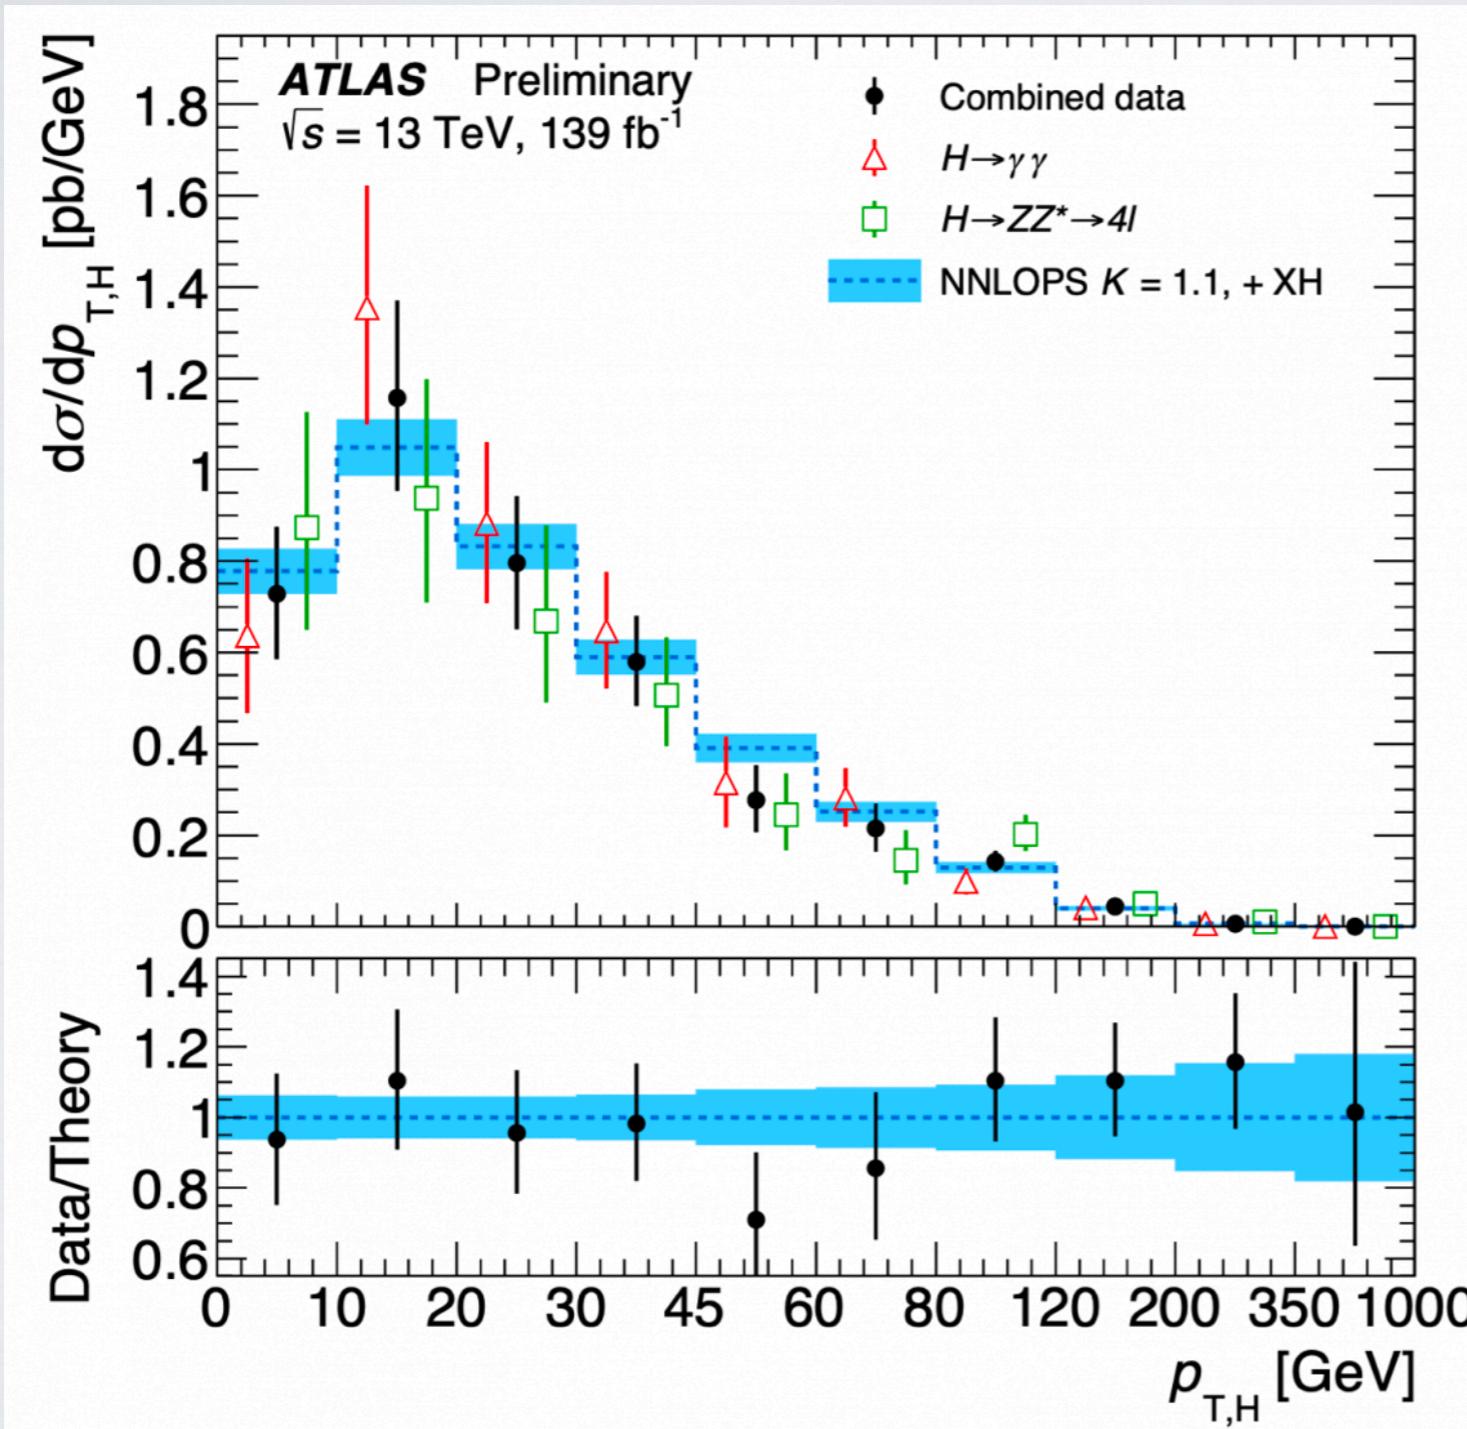

$$C_F = \frac{N_c^2 - 1}{2N_c}$$

can use this to extract α_s from data $\Rightarrow \alpha_s(m_Z) = 0.1226 \pm 0.0038$

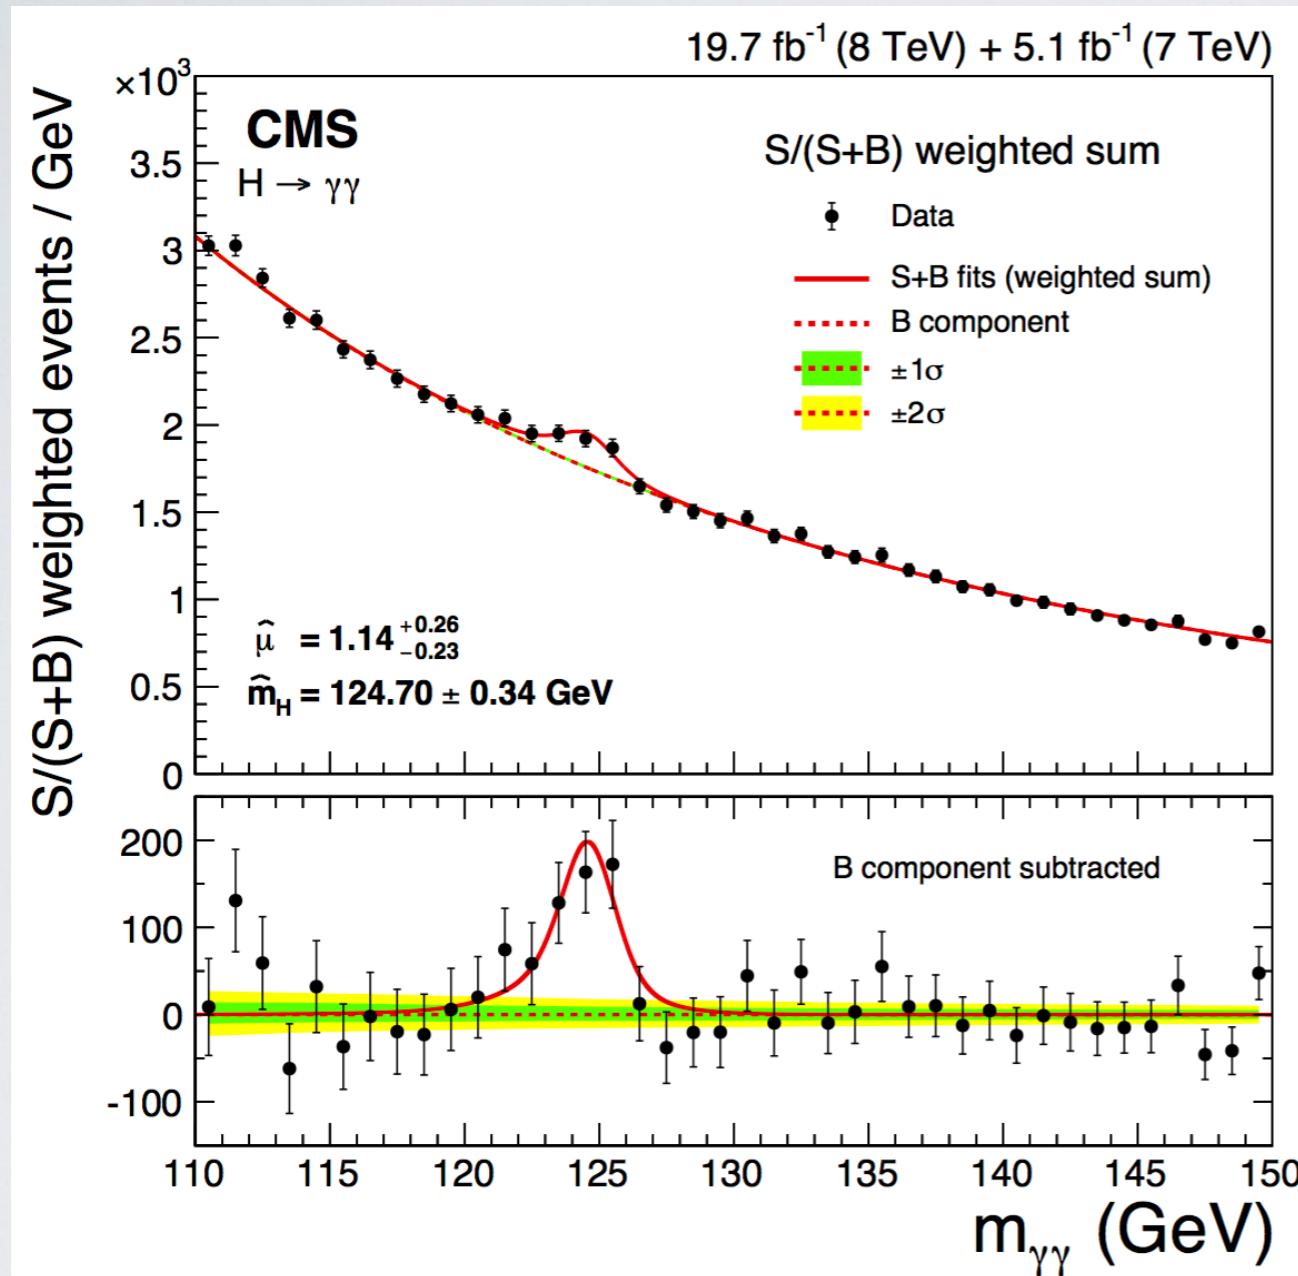

Current Standard Model Tests

Differential tests offer more information

Finding new particles

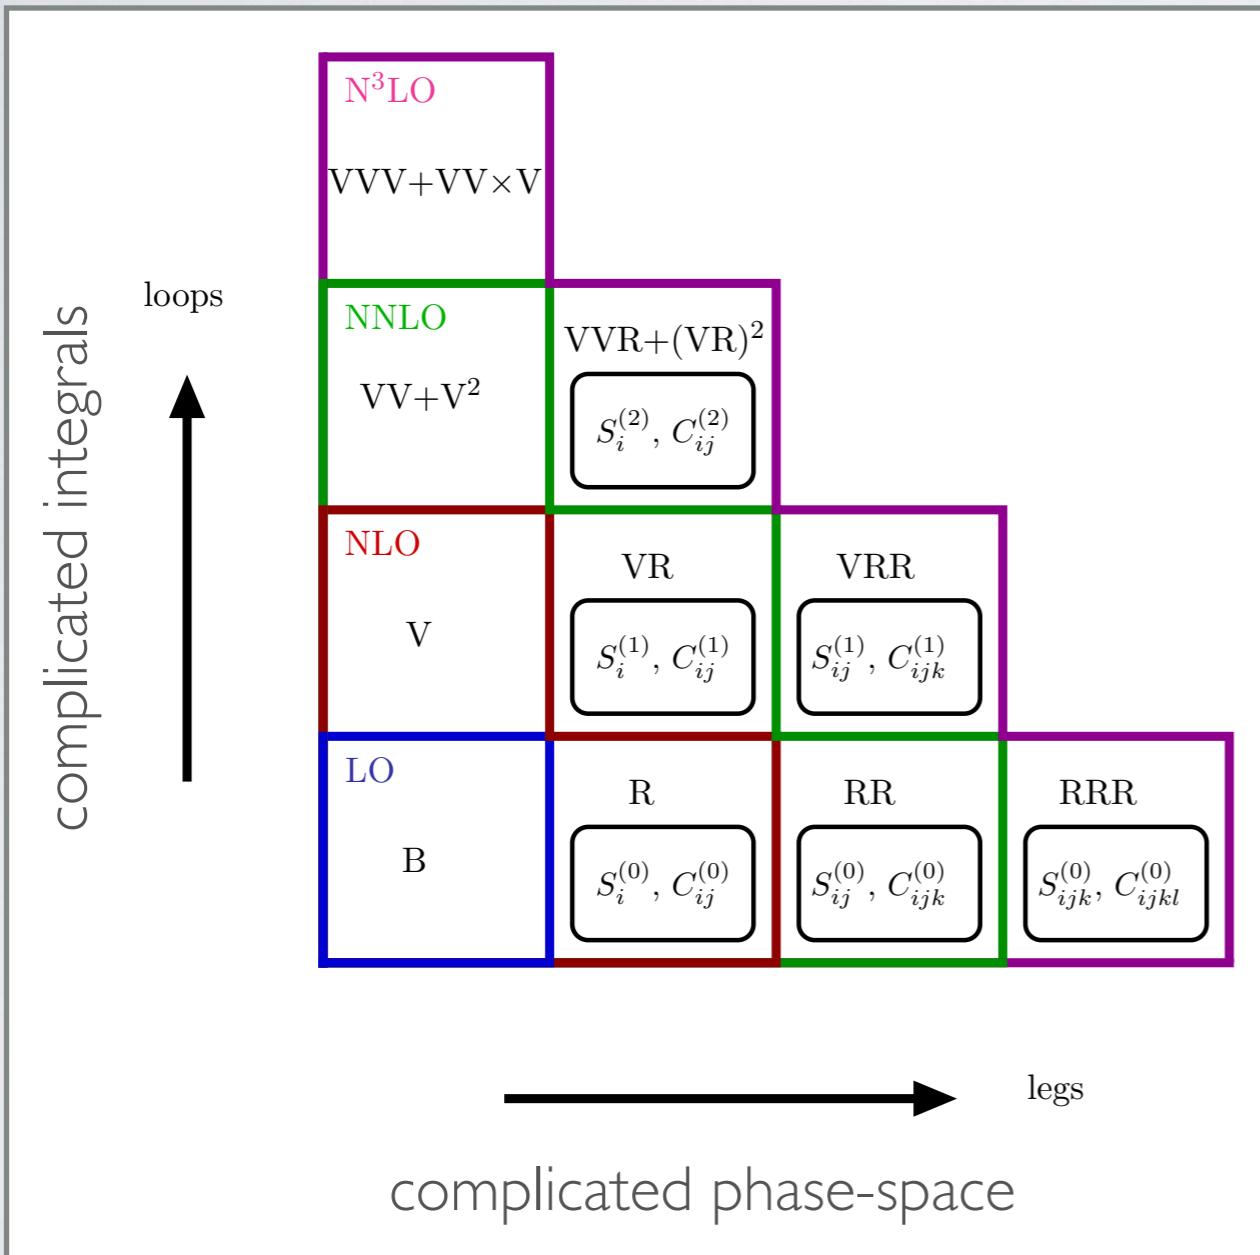

bump hunting is relatively easy

$$\mathcal{A} \sim \frac{1}{p^2 - m_h^2 - im_h\Gamma_h}$$

leads to the
Breit-Wigner distribution

Γ_h = decay width

Precision fixed order calculations

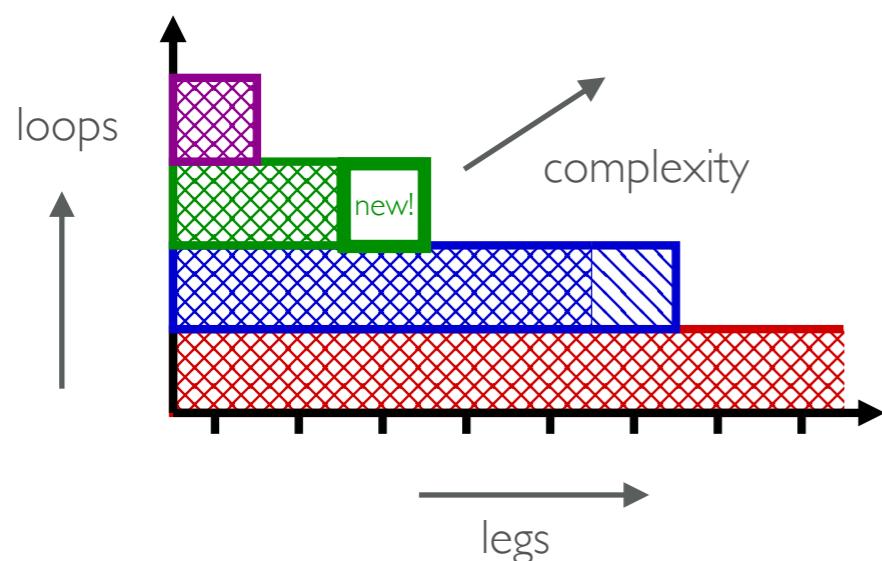

$$d\sigma \left(\text{black circle} + X \right) = \text{one loop} + \text{two loops} + \text{three loops} + \dots + \mathcal{O}(\alpha_s^8)$$

keeping theory in line with experiments takes **years** of dedicated effort

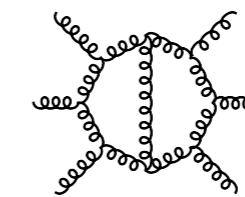

Growing Complexity

loops	1	2	3	4	5
diagrams	5	30	450	50,000	1.5×10^6
year	1973	1974	1980/1993	1997/2005	2016

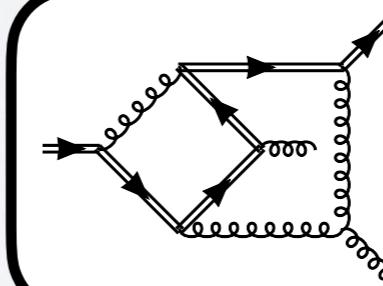

Diagrams contributing to QCD β function up to 5 loops

more scales = more complicated

algebraic complexity
e.g. six-gluon scattering

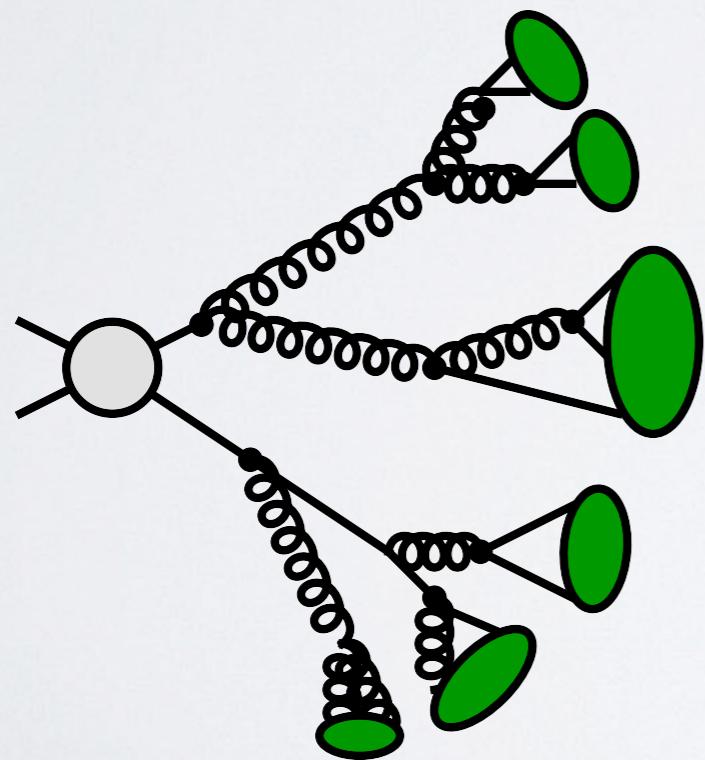

analytic complexity
e.g. $p\bar{p} \rightarrow t\bar{t}$

More radiation: e.g. parton showers

The cancellation of IR divergences is connected to the universal singular behaviour of QCD

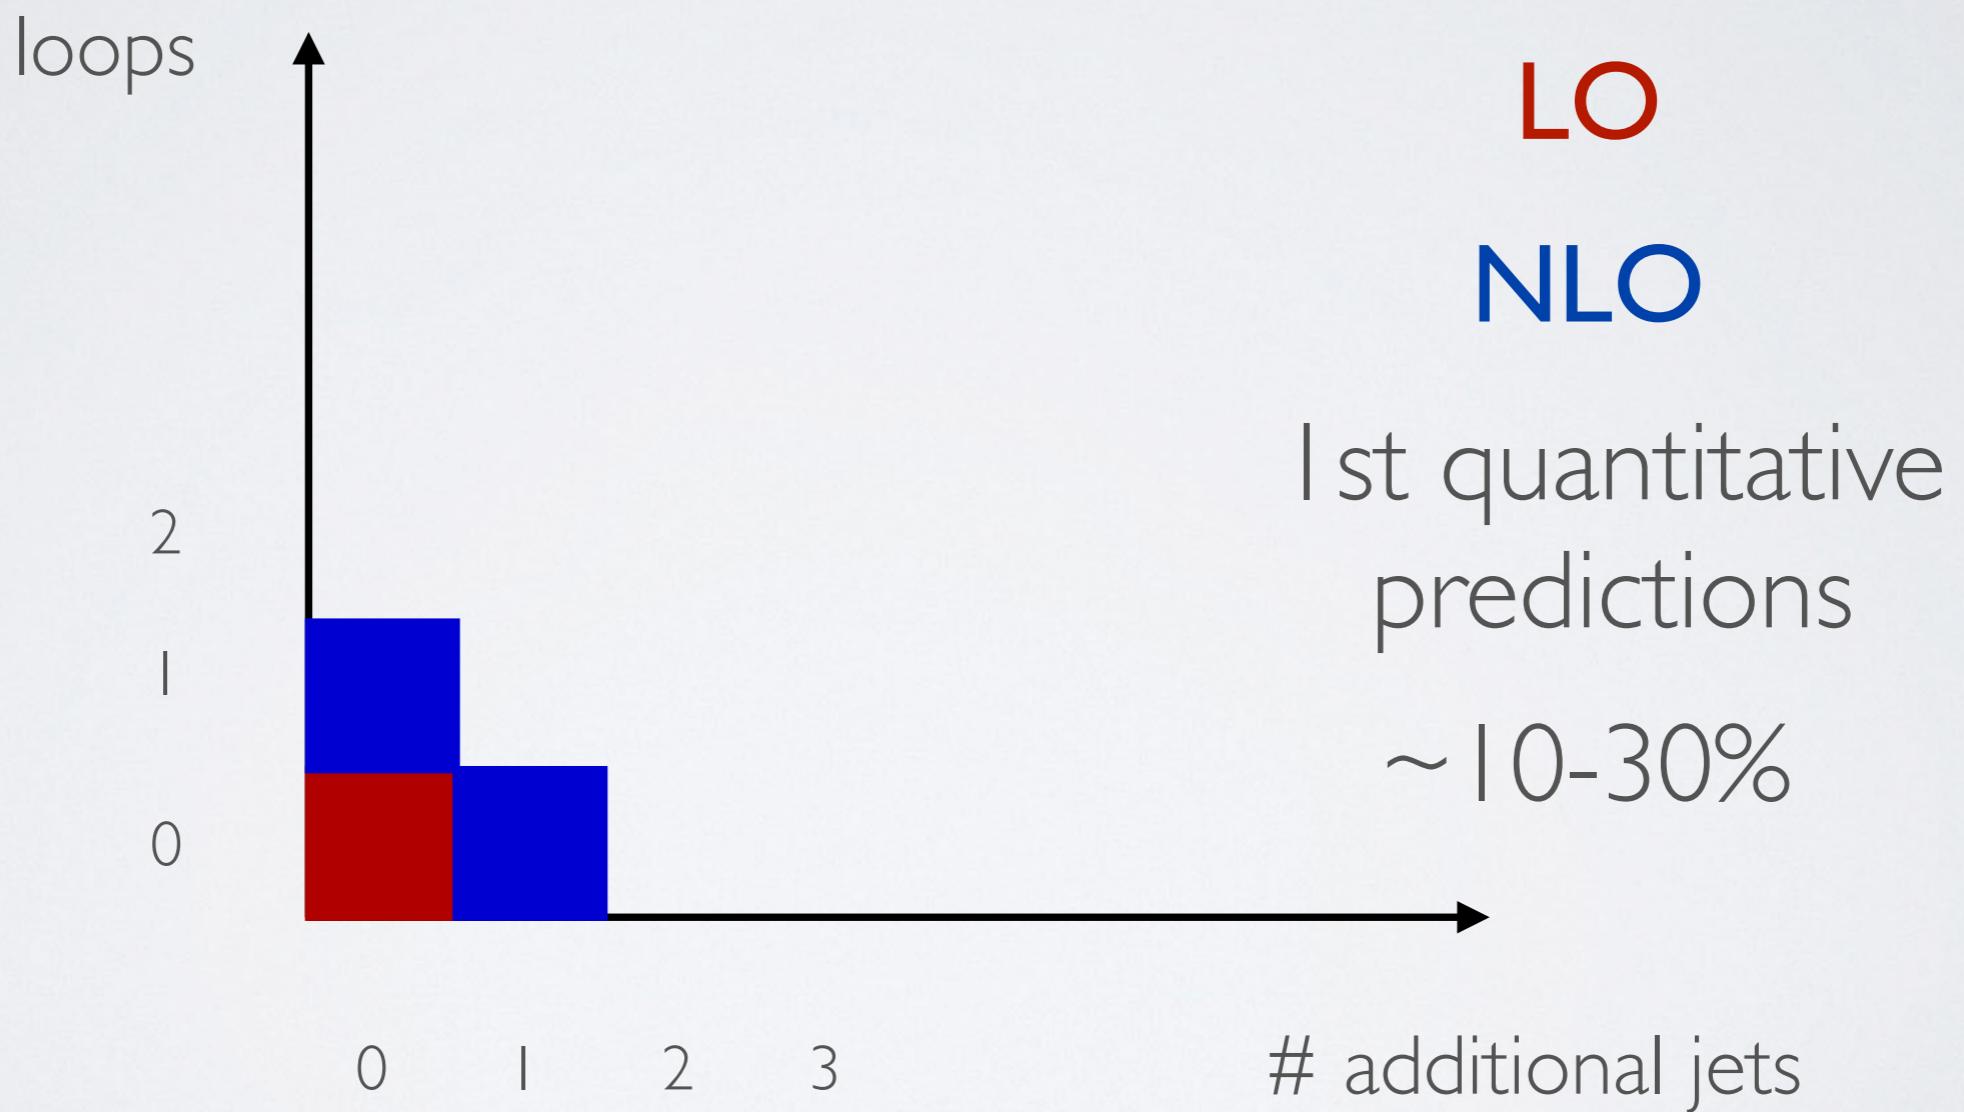

The probability of a parton emitting a soft or collinear gluon is independent of the hard scattering process

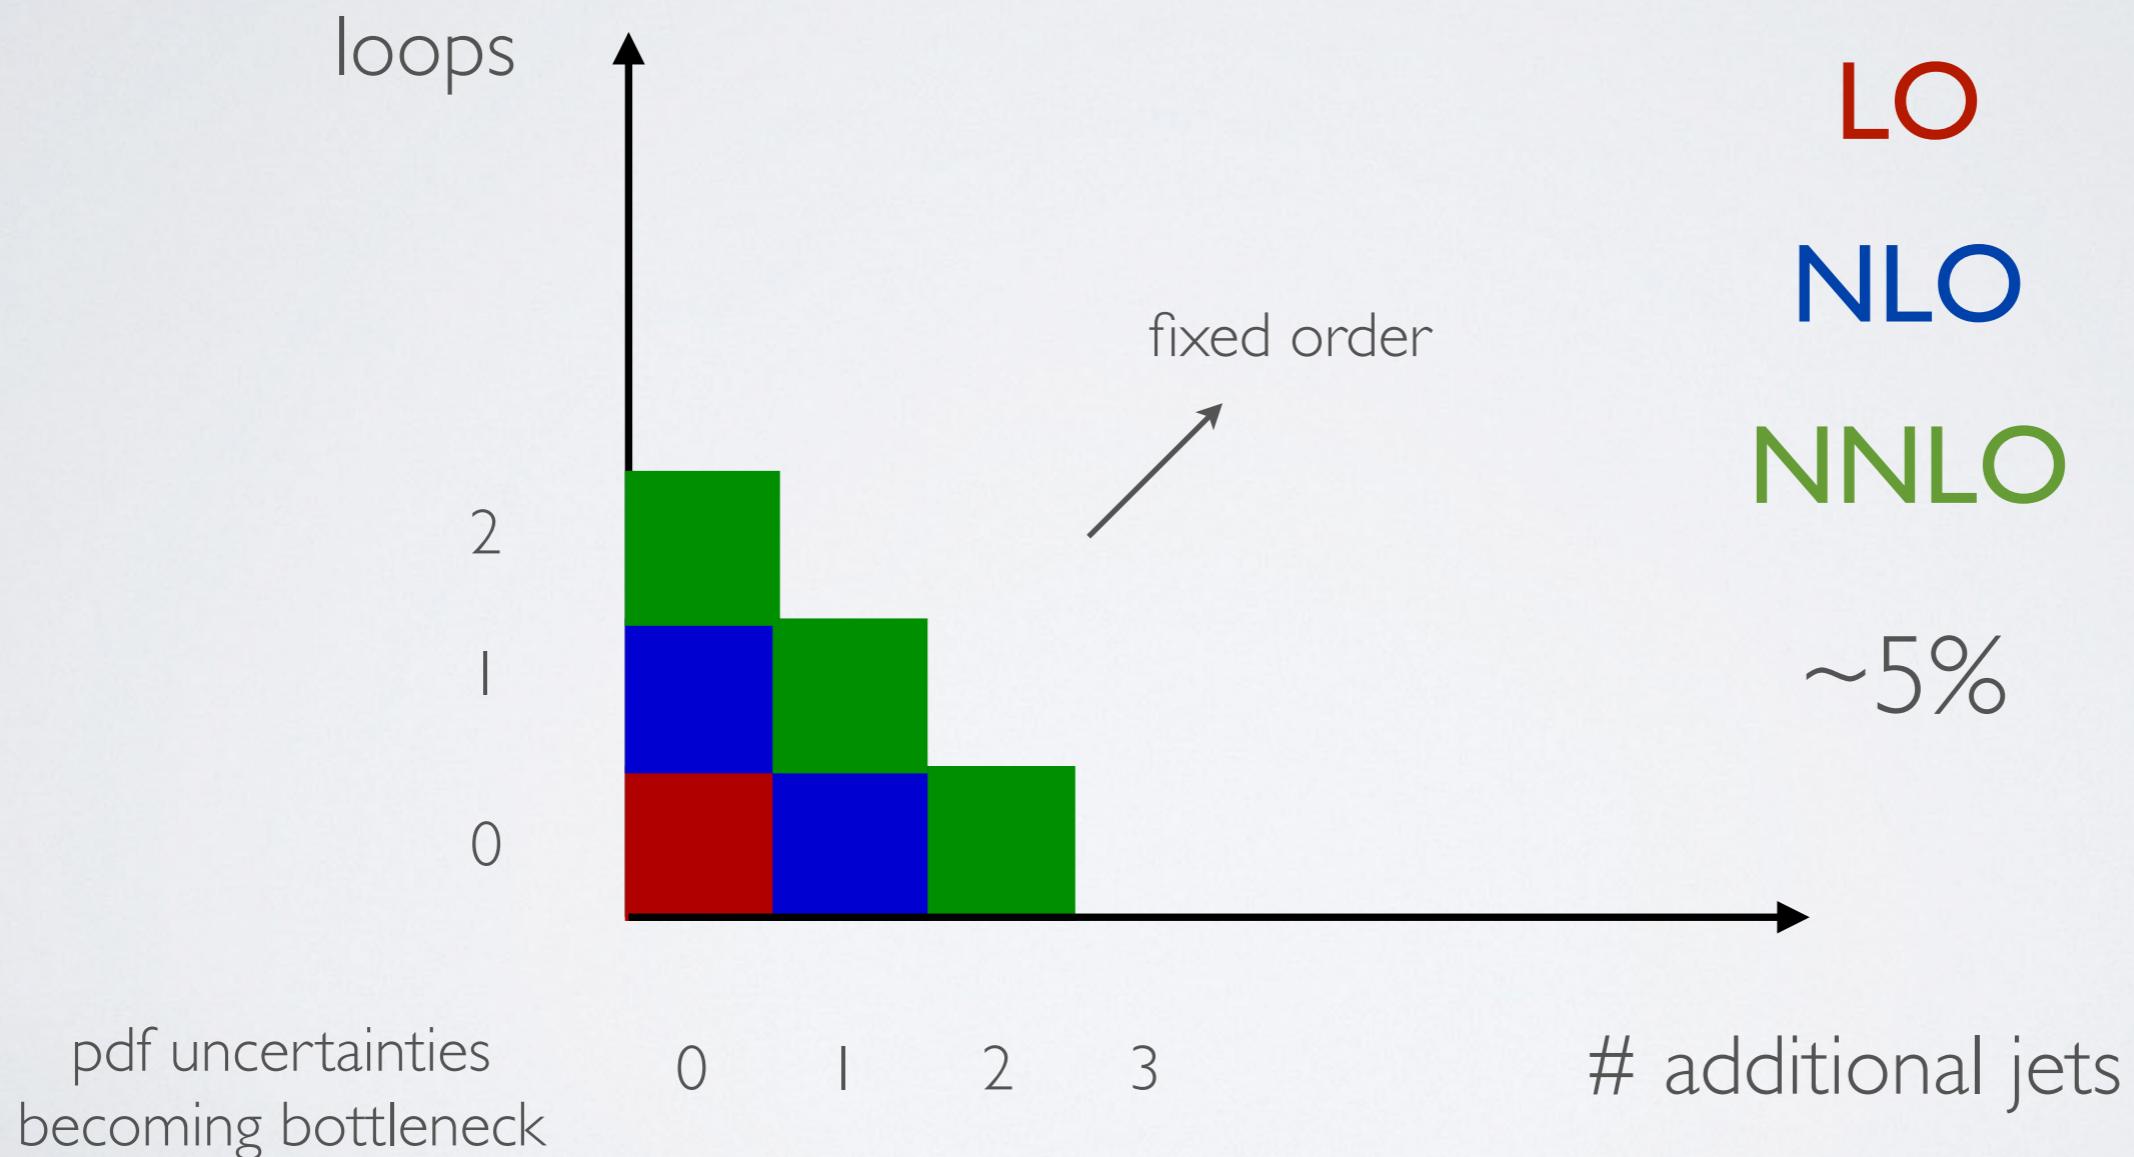

parton showers give a statistical evolution of the hard scattering process until the hadronisation scale is reached

the effect is an explicit re-summation of soft emissions **beyond fixed order** perturbation theory

Ingredients for precision

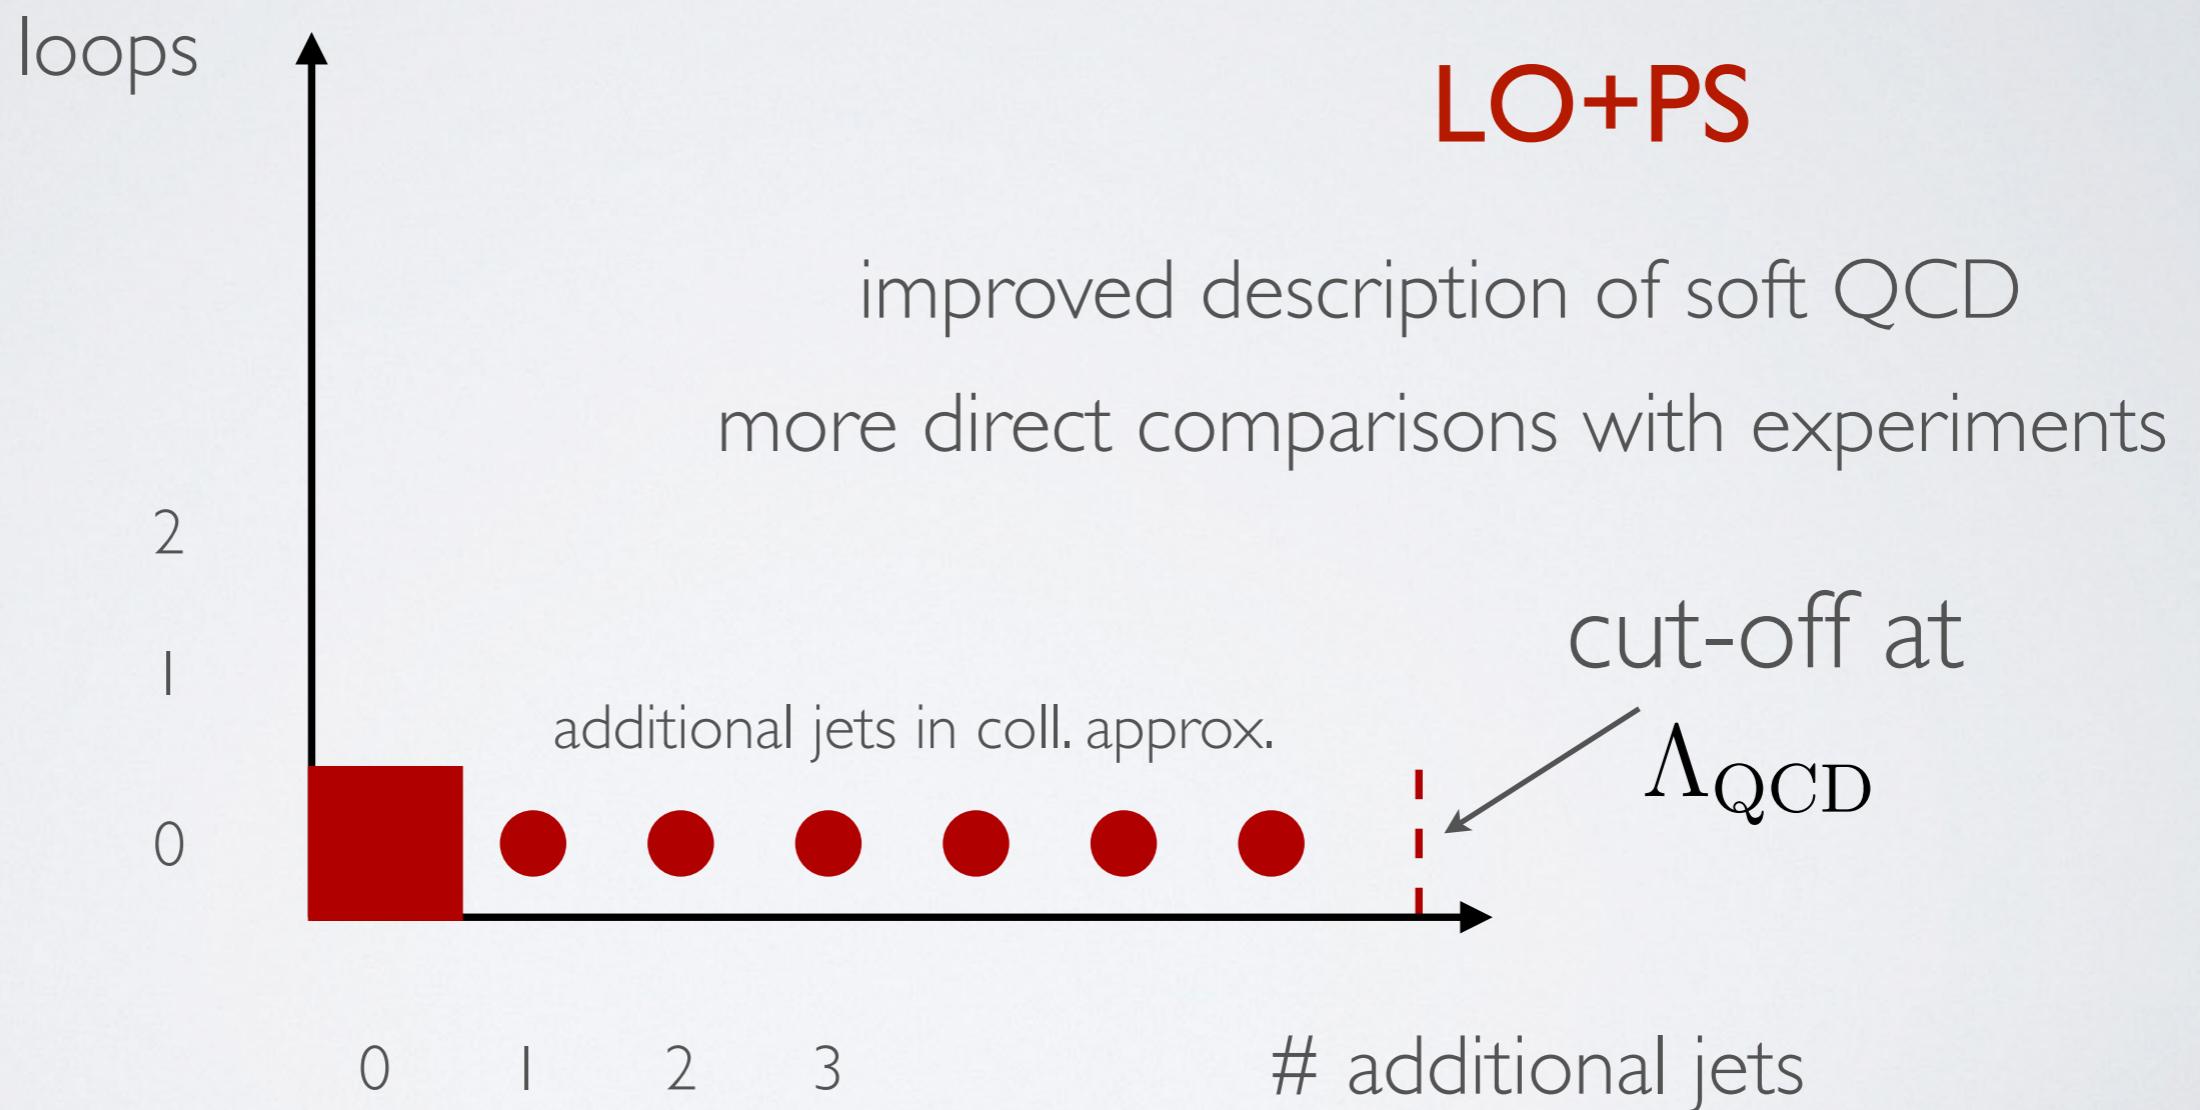

Ingredients for precision

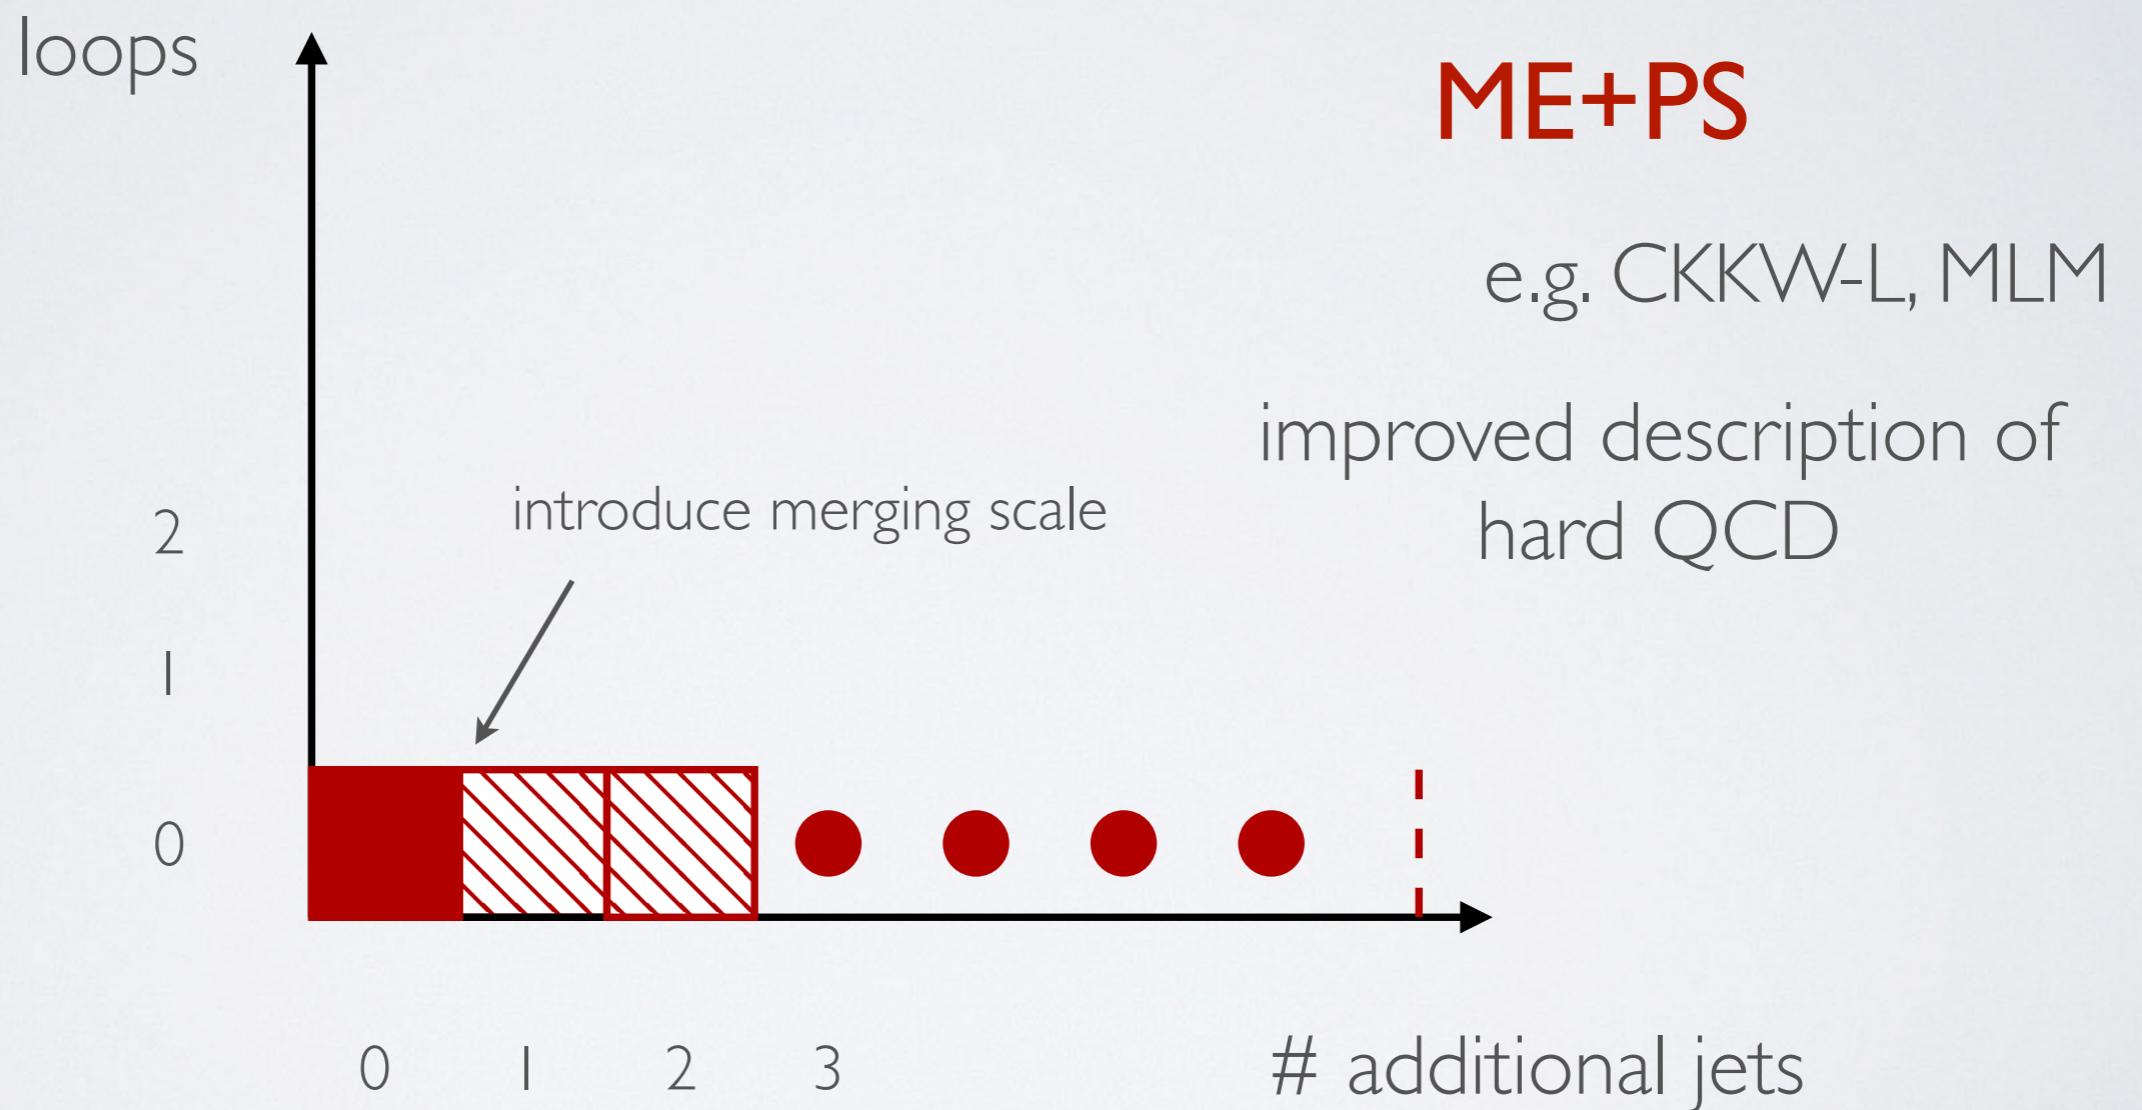

Ingredients for precision

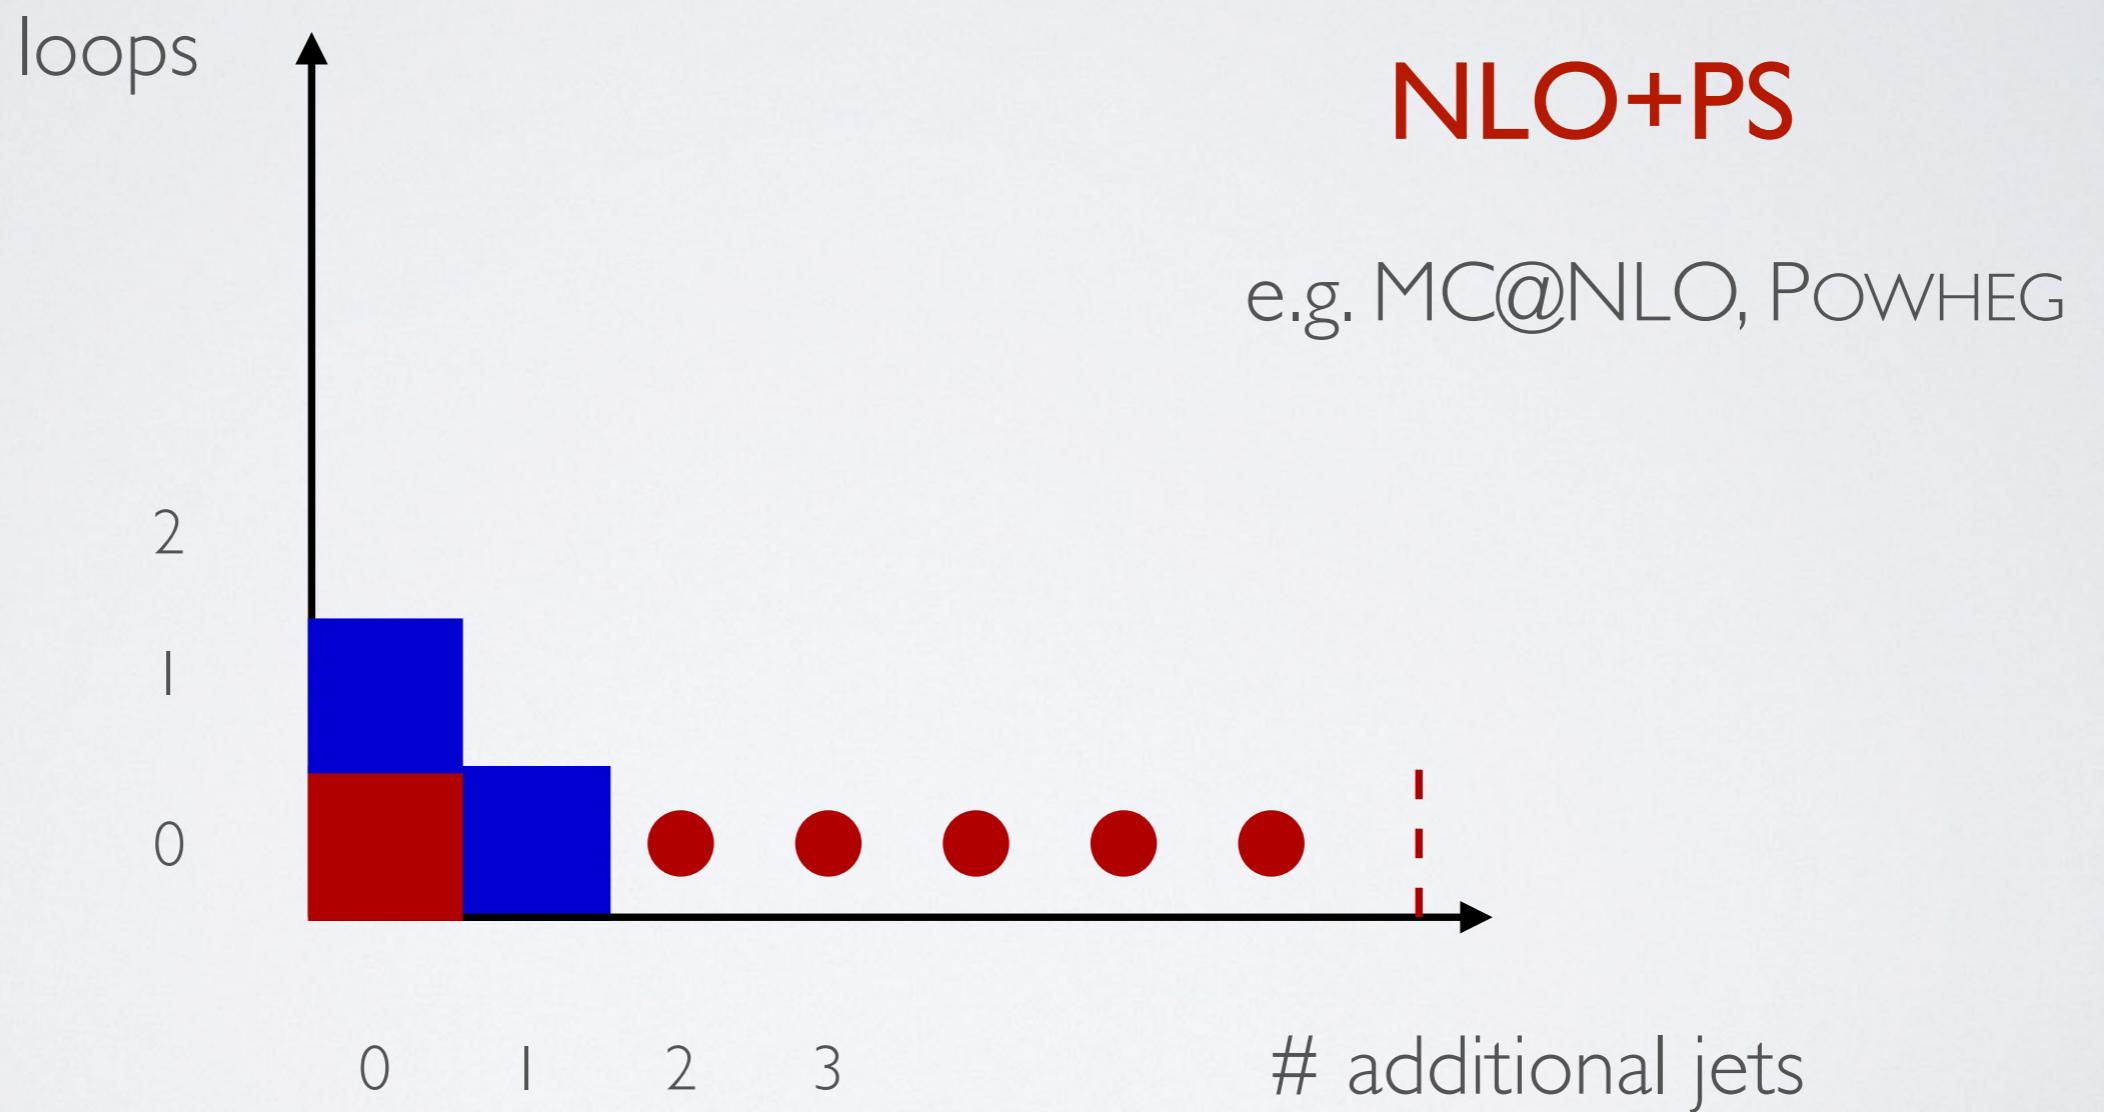

fixed order not good for all regions

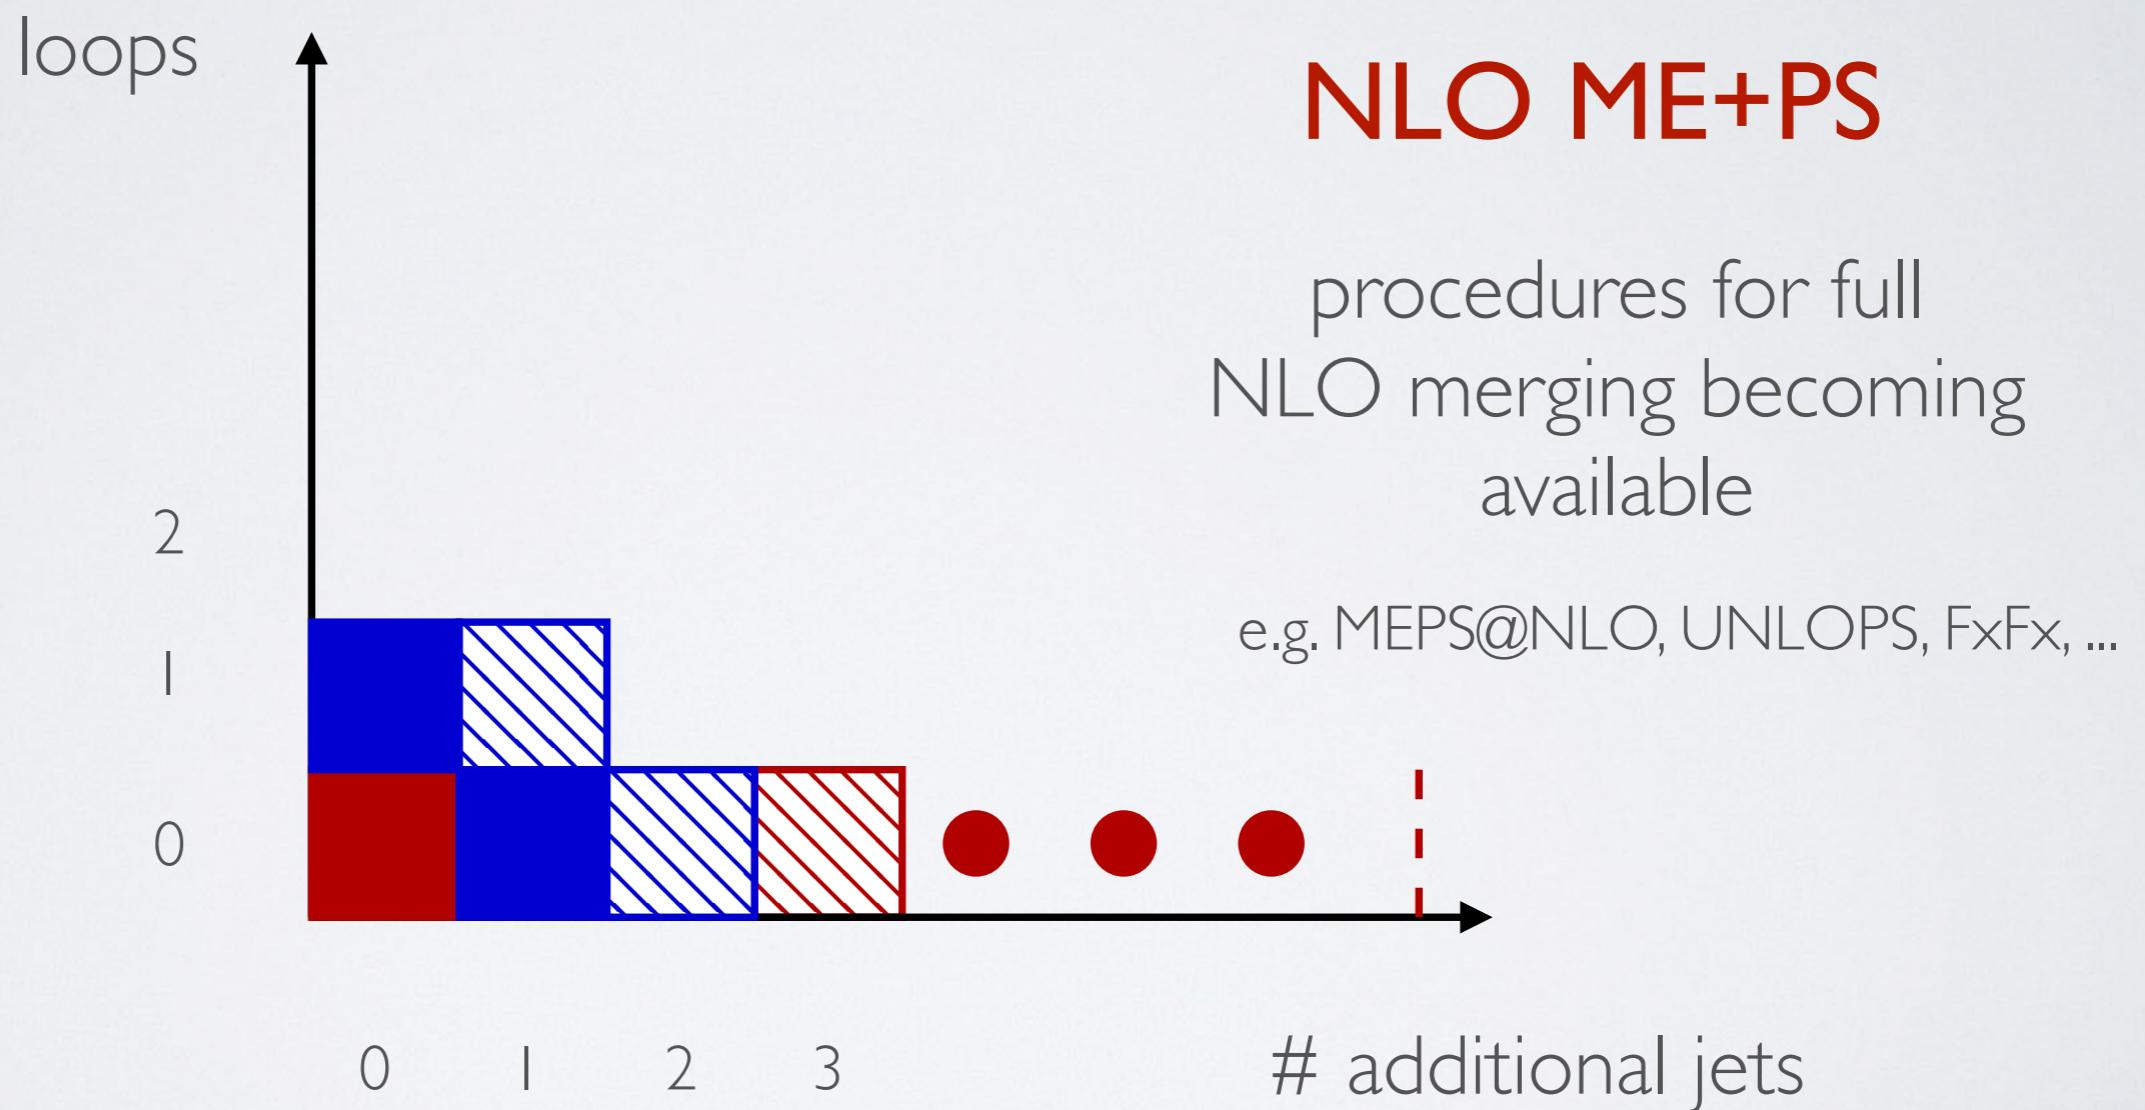

Ingredients for precision

Ingredients for precision

Ingredients for precision

General purpose event generators (long term projects)

Pythia (1982-)

Herwig (1986-)

Sherpa (2002-)

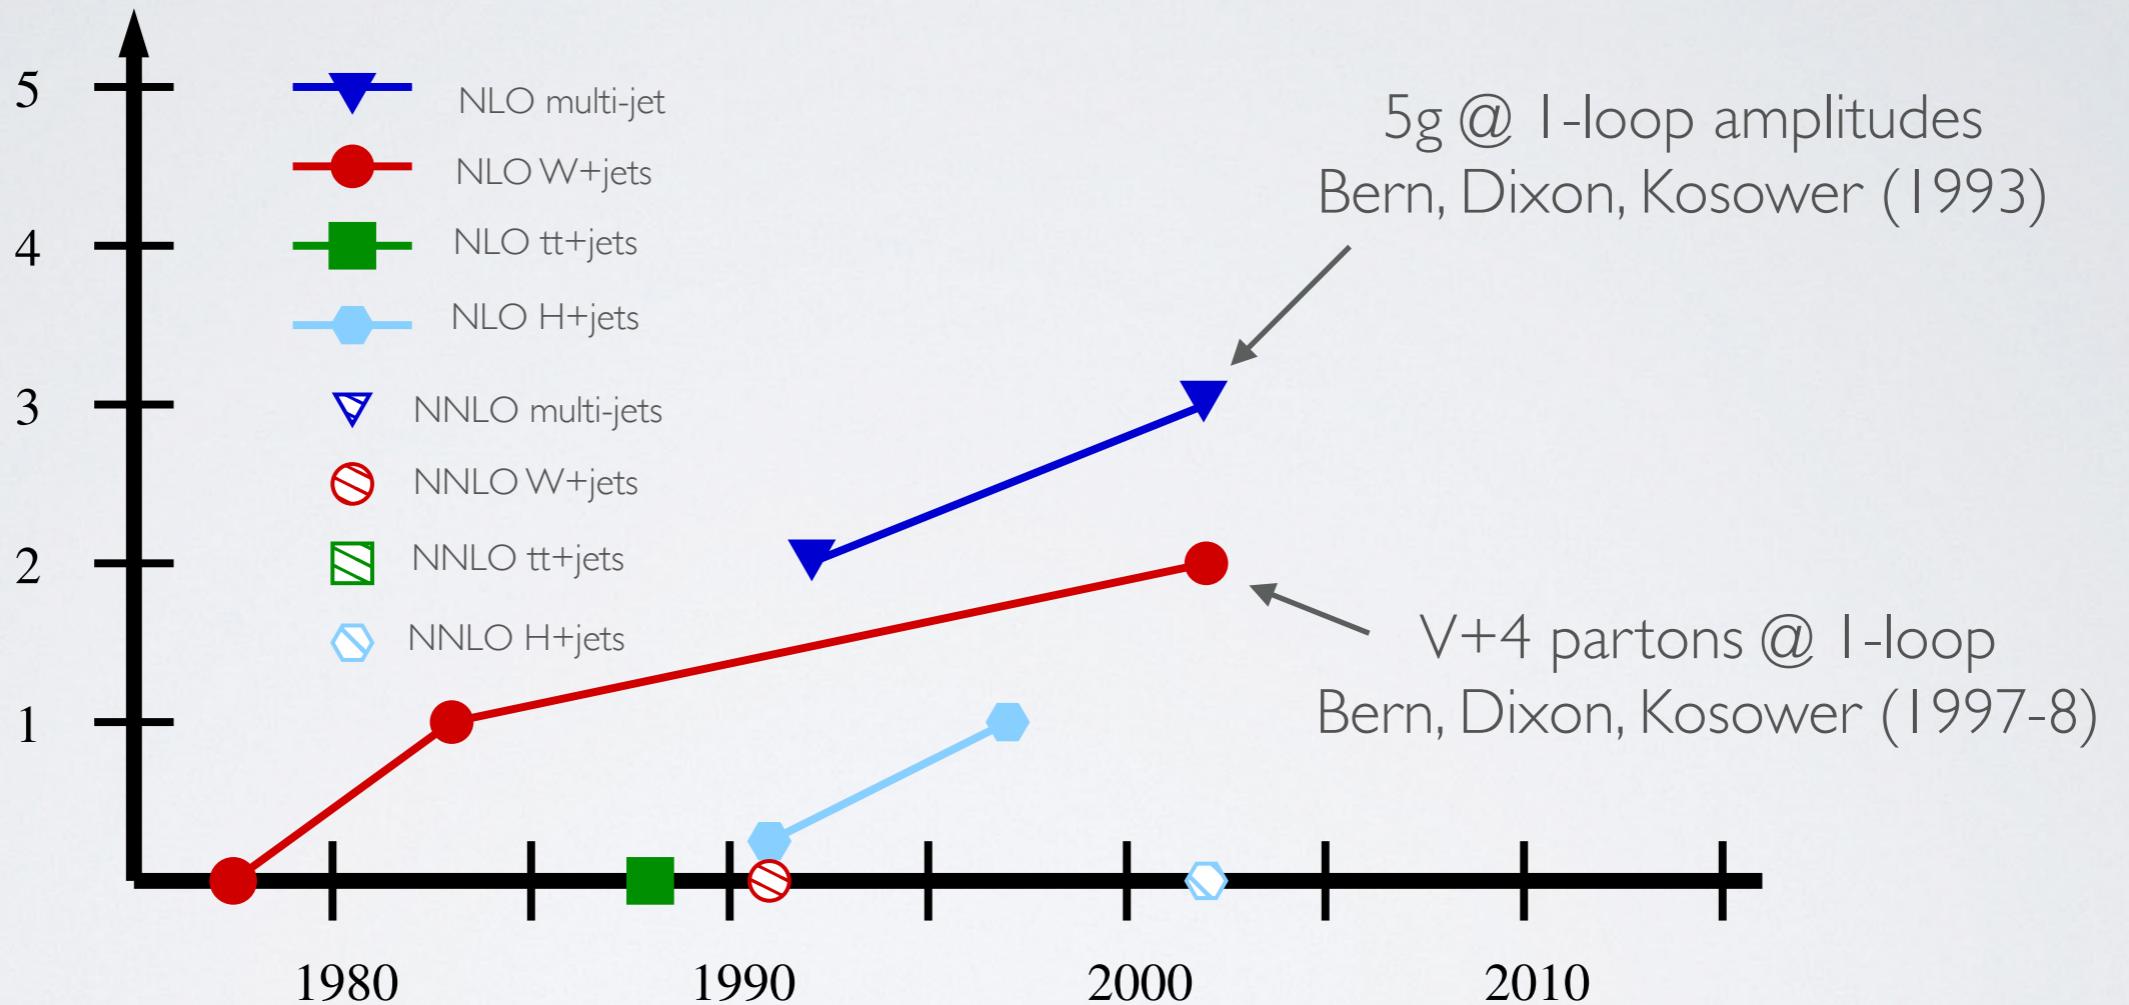

Powheg (2004-)

MadGraph (1994-)

collect large numbers
of different models
(hadronisations,
parton showers etc.)
and interface with
specialised codes for
PDFs, amplitudes etc.

Chi ha usato uno di questi generatori prima?

a bit of history

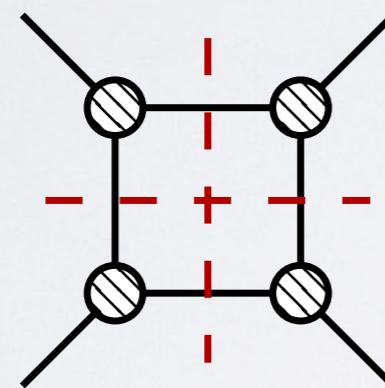

Loop corrections not the only issue: another breakthrough in mid 90's was IR subtraction technique of Catani and Seymour

new theoretical methods

~2005 one-loop basis
integrals were known

't Hooft, Veltman, Denner, Dittmaier, Bern, Dixon,
Kosower, Ellis, Zanderighi, van Hameren, ...

$$\text{Diagram} = \sum_{t \in \text{boxes}} c_{4;t} \text{Diagram}_1 + \sum_{t \in \text{triangles}} c_{3;t} \text{Diagram}_2 + \sum_{t \in \text{bubbles}} c_{2;t} \text{Diagram}_3$$

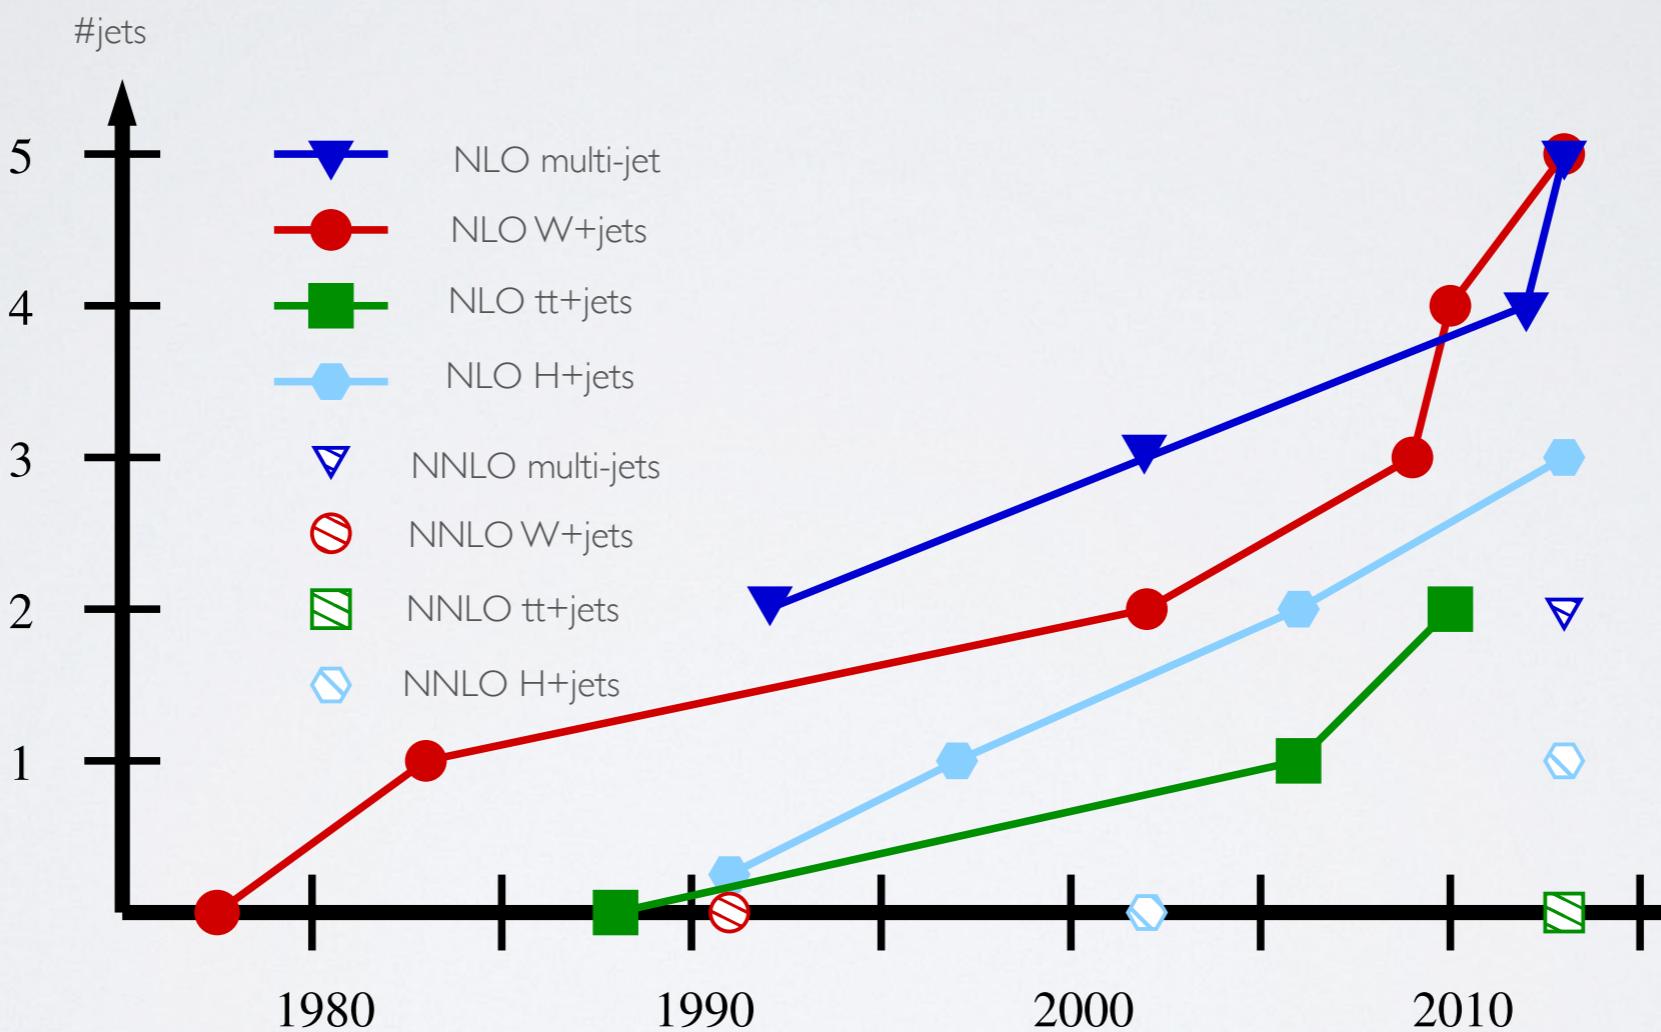

new algebraic algorithms -
multi-scale bottleneck overcome!

Ossola, Papadopoulos, Pittau, Bern, Dixon, Kosower, Berger,
Forde, Ita, Maitre, Ellis, Giele, Kunszt, Melnikov,
SB, Biedermann, Uwer, Yundin, Mastrolia, Cullen, Greiner,
Heinrich, Luisoni, Ossola, Peraro, Reiter, Tramontano,
Pozzorini, Cascoli, Maierhöfer, ...

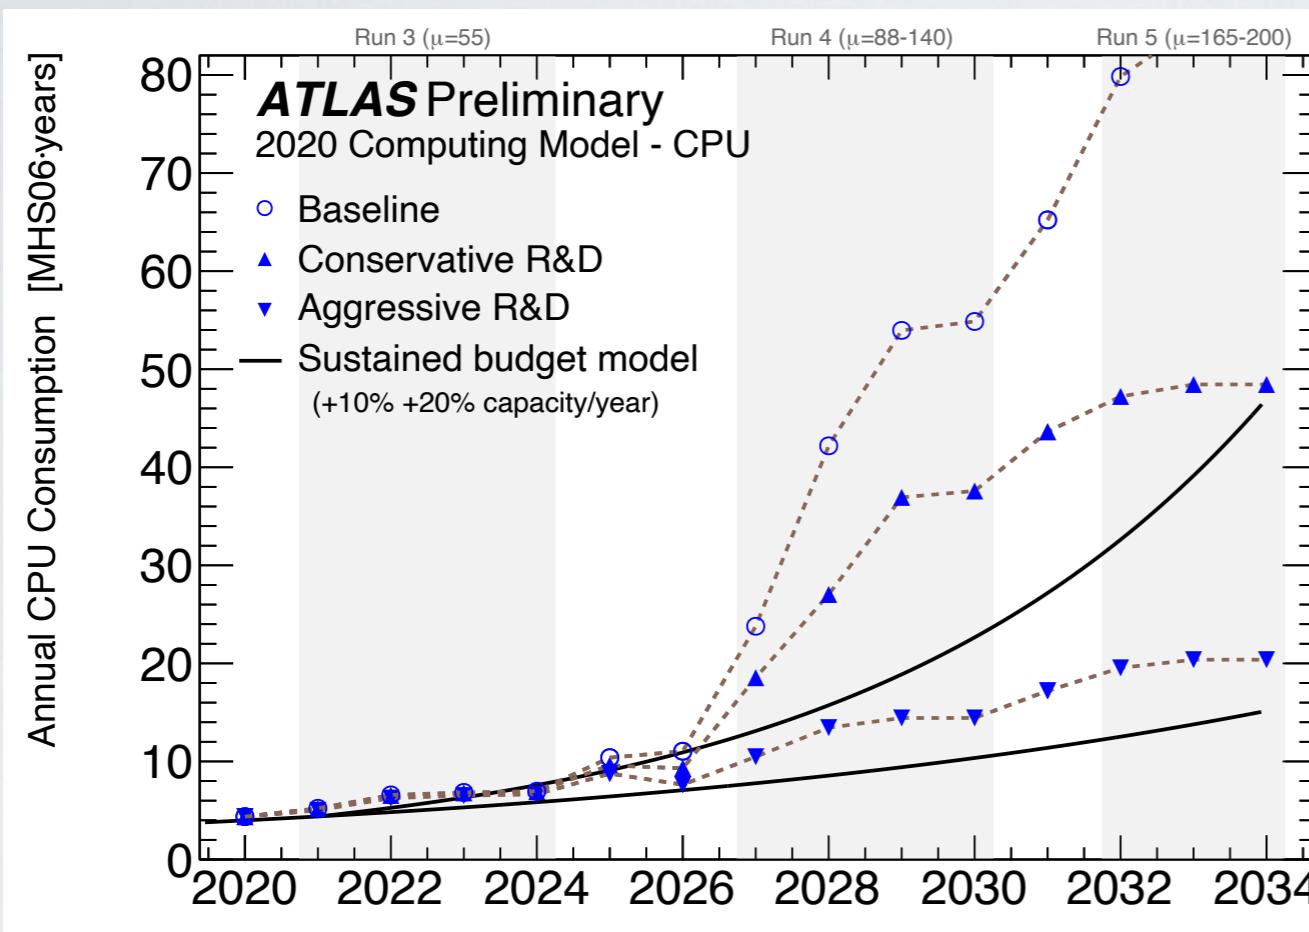

performing algebra numerically led to **automated**
codes capable of $2 \rightarrow 5/6$ processes at NLO.
HELAC-NLO, BLACKHAT, GO SAM, NJET, RECOLA, MADLOOP, OPENLOOPS

NLO QCD corrections in 2013

what's the computational cost?

LHC MC computing requirement projections

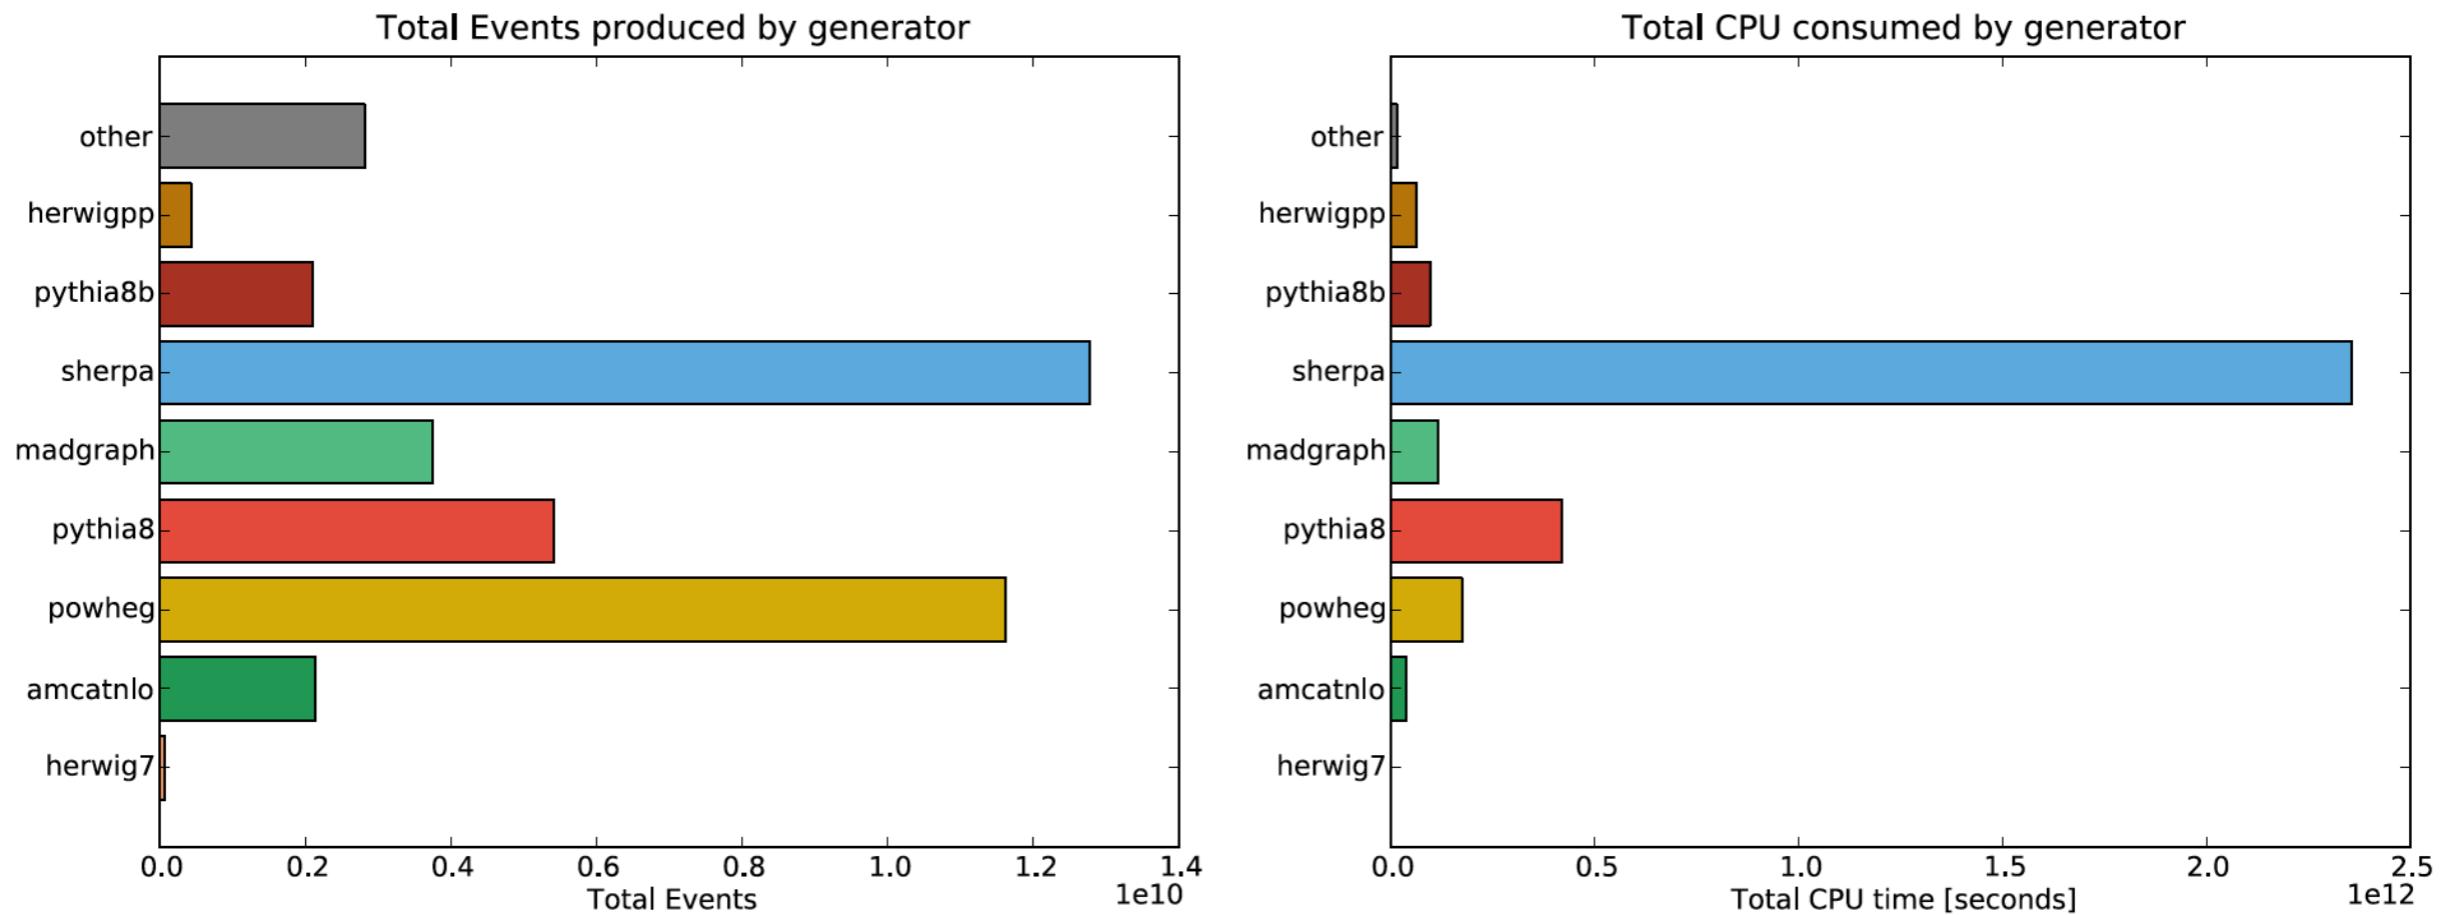

- Moore's Law no longer applies
- HL-LHC could have limitations from MC statistics without new developments

from
Christian Güttschow
at
Taming the accuracy of event generators
workshop CERN, June 2020

Breakdown by generator (bit outdated, but not too bad)

- left plot: does not account for alternative multi-leg setups
- right plot: most CPU spent on high-precision multi-leg calculations
(e.g. for ATLAS: $V + 0, 1, 2j$ @NLO+3, 4j@LO and $t\bar{t} + 0, 1j$ @NLO+2, 3, 4j@LO)

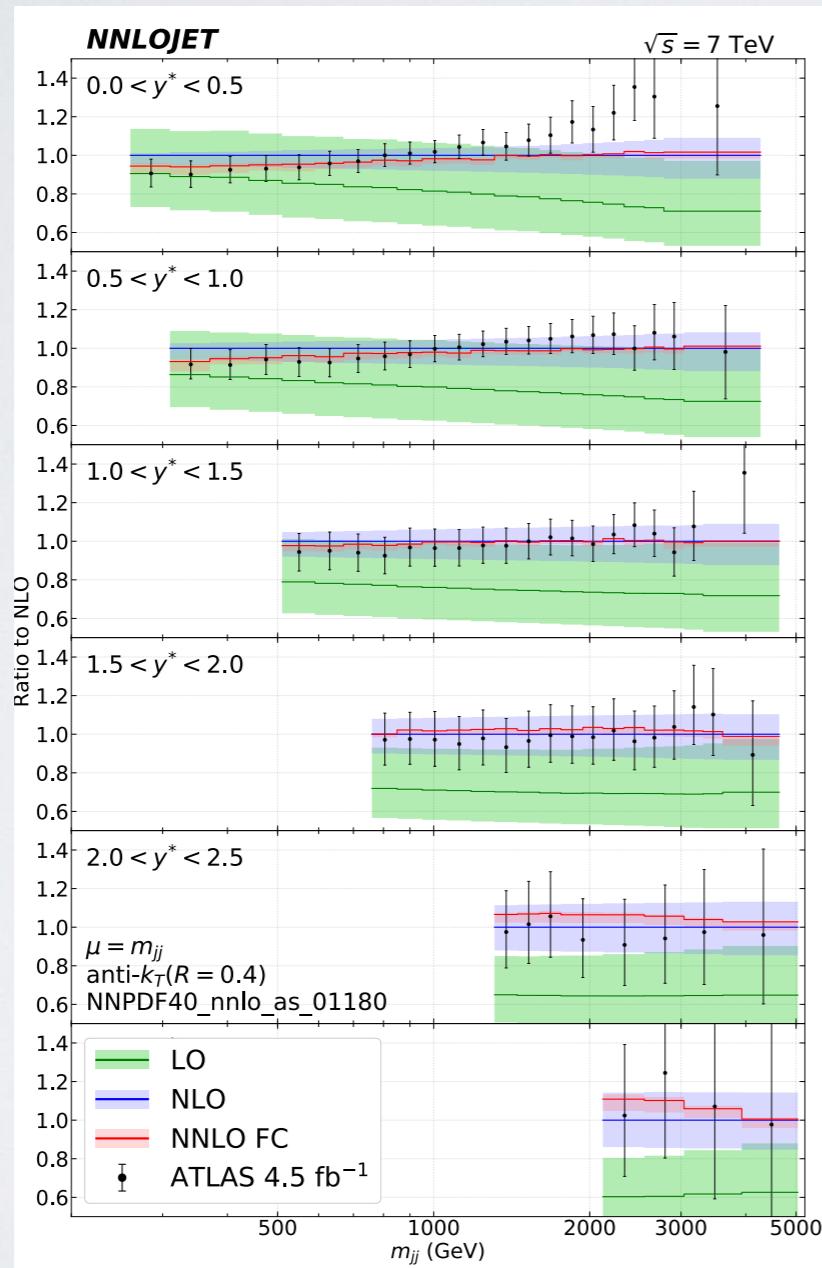

[courtesy of Josh McFayden]

- outlook: CPU spent on expensive setups expected to increase faster than for fast setups

and for NNLO precision?

many are still specialized (private) codes, NNLOjet, MATRIX, etc.

for some of the most expensive
fixed order simulations

~ 200,000 CPU hours

example: full colour di-jets [Chen et al 2204.10173]
